The suggestion that continuous fins can be made as efficient as noncontinuous fins by increasing the fluid velocity with the former fin arrangement within allowable over-all pressure-drop limitations warrants detailed consideration.

From Equation [9] of the paper, it will be seen that pressure drop (ΔP) normally varies as the square of the linear velocity V. Further, the slope of the (L/D_h) lines in Fig. 3 is $-2/3$, whence it can be said that h_f varies as $V^{-2/3}$ (since $V = G/\rho$ in the abscissa; $R_h = GD_h/\mu = V\rho D_h/\mu$), referring to Equation [5].

Taking $R_h = 30$ (in Fig. 3), for example, we find $J_A = 0.028$ for a 10-ft length of continuous fins (sample A-1), as against $J_A = 0.056$ for a similar length on a noncontinuous basis (sample A-9); also, $\Delta P_{A-9} = 1.5\,\Delta P_{A-1}$, from Fig. 2. The foregoing, then, for a given condition, represents a 100 per cent increase in h_f with only a 50 per cent increase in ΔP, for noncontinuous (A-9) versus continuous (A-1) longitudinal fins.

Since $\Delta P_{A-9} = 1.5\,\Delta P_{A-1}$ from Fig. 2, V for A — 1 can be increased only 23 per cent to stay within equivalent pressure-drop limitations. The increase in h_f from this would be less than 10

[7] "Heat Transfer and Pressure Drop of Liquids in Tubes," by G. E. Tate and E. N. Sieder, *Industrial and Engineering Chemistry*, vol. 28, 1936, pp. 1429–1435.

per cent and the effect on fouling rate from, say 5 up to 5.5 fps would not be appreciable.

Professor Short's comments are of interest. The confusion with respect to the use of fouling factors in Fig. 5 as reciprocals of fouling resistances is natural if one is accustomed to the use of the resistance forms. However, from practical everyday rating experience in the heat-transfer engineering industry, the authors have found the coefficient form of fouling factors a more convenient system with which to work.

The suggested use of Reynolds numbers incorporating a dimension in the direction of flow was considered when preparation of the paper was begun. However, since the preliminary work had been carried well along on the conventional basis before any thought of publication existed, dead-line limitations did not permit of a transposition to the suggested form of presentation, and this work was necessarily left for study at some more opportune time.

The authors are in complete agreement with Professor Short's precautionary remarks on the free use of data from tests with odd-shaped flow passages. As pointed out in the paper, various factors exist to which careful consideration must be given in applying test data to actual use outside the range of the original work. It must be stated that $J_A'/(f/2)$ relationships were included in the present paper reservedly, merely to indicate the comparison of the results of this investigation with previously published data.

Mr. Sieder's discussion is most timely. The savings in scarce and strategic materials through the use of noncontinuous fins is well worth while, since increases in over-all rate up to 100 per cent, after applying nominal fouling factors of $h_D = 200$, are achieved. The value of these factors is readily obvious on new installations. On continuous-fin double-pipe equipment already in service, noncontinuous-fin tubes could be installed and, depending upon service conditions, up to one half of the units in the original battery could be released for other work.

It is regretted that certain restrictions prohibited a more detailed presentation of the original test results. However, it was felt that sufficient data were included to indicate generally the conclusions arrived at through this investigation.

The apparent shift in the start of the transition region, as indicated by this work and suggested by the earlier data of Davies and White (6), was revealed primarily for the record and not as a final conclusive fact. As noted in the paper, the tests were made to simulate plant-scale conditions, with no calming sections and greater temperature rises in most cases than the usual 2-4 F used in normal laboratory work.

These factors no doubt are partly responsible for the shifting of the transition zone, as observed. However, since this work was undertaken for the essential purpose of producing practical rating curves, and since the aforementioned factors are normally present in actual operations of plant-scale equipment, the use of the data established by these tests as against the more theoretical values from laboratory-scale experiments should result in ratings which more nearly approach the desired plant-equipment performance.

Protecting Buried Metals Against Corrosion

By STARR THAYER,[1] HOUSTON, TEXAS

The author mentions briefly the various types of corrosion from the standpoint of methods used to combat it. His main concern, however, is with underground structures, such as pipe lines, which suffer a corrosion loss of upward of $100,000,000 yearly. Protective coatings have been developed which constitute a long step toward elimination of pipe-line corrosion, when applied to new pipe. Older lines can be protected by a cathodic process, based on correcting the galvanic differences in potential between small sections of the pipe wall, or changes in soil conditions. The process of making the pipe cathodic to the surrounding soil is described, illustrations of the practical effects of the method being given.

Introduction

PROBABLY there is no way of knowing actually how much we as a nation pay annually as tribute to corrosion. It has been estimated by some that one half of all of the iron mined is used to replace that lost through corrosion. One reliable estimate places this loss for the pipe-line industry alone in excess of $100,000,000 per year. This much is certain; we know that it is a very great national loss, larger than our losses from either floods or fires. There is nothing spectacular about a piece of rusty iron so it has received practically no national prominence. Perhaps an "anticorrosion week" would be as appropriate as our "fire-prevention week."

The elimination of these losses is an important undertaking at any time. During this time of national emergency, when all metals are so vitally needed in industry, it should be apparent that this work is of utmost importance.

Types of Corrosion

For convenience, we may separate the different kinds of corrosion into classes having to do with methods of prevention rather than with causes. Thus, we would have loss of metal from above-ground structures, or atmospheric corrosion, corrosion of industrial equipment, and corrosion of buried or submerged structures. The first two classes are approached from an entirely different angle from the third. Atmospheric corrosion is almost always combated with paints or a selection of materials such as copper for roofing material, and galvanizing for sheet iron and pipes. Industrial corrosion is generally combated to some extent with paints, but more often with a selection of materials. There are so many examples of this type of corrosion that only a few can be discussed here. Heat exchangers have come in for considerable attention. To date, the only practical method of reducing corrosion in such equipment is by the selection of special metals for the tubes. Losses in brine lines may be mitigated by confining the construction to only one kind of metal. If the line is constructed of steel, then all valves and fittings should be of the same material. Galvanic couples will be created if this is not done and one metal will suffer.

The elimination of corrosion in the case of buried or submerged structures, which is the principal topic of this paper, will be discussed more fully.

Underground Corrosion

The one single type of construction most exposed to underground corrosion is the pipe line. Probably more effort has been made to eliminate corrosion on these lines than in any other industry. With more than 130,000 miles of lines well scattered throughout most of the country, it is only natural that corrosion has become a serious problem. In most instances, the methods used in combating this corrosion can be applied to other underground or submerged structures, such as steel piping for other purposes, sheet piling, underground tanks, etc. This problem may be attacked by one or more of the following methods.

Selection of Materials. Some success has been had with the use of materials other than steel in eliminating underground losses. Copper pipe has been used with success in small sizes. Lead has been used as a covering for cables, with a minimum of trouble. Ceramic materials have lately been used for water lines and apparently will be satisfactory. However, pressures are limited with all of these. It is still necessary to use iron or steel when large volumes or high pressures are involved. At this time, there is nothing to indicate that a corrosion-resisting ferrous material will soon be available. Therefore the problem is reduced to making the iron or steel last as long as possible.

Selection of Right of Way. In laying pipe lines, it is sometimes possible to avoid known corrosive areas by selecting a more favorable location for the line. Swampy areas are sometimes avoided by going around them. Often, lines are built on trestle work to avoid laying them in a bad soil. It is the author's opinion, however, that these measures are not justified if any extra expense is incurred, and if it is done merely to avoid corrosive soils.

Protective Coatings. When corrosion is even suspected, it is common practice now, with most pipe-line companies, to apply a protective coating to the pipe. A few companies make it a practice to coat all lines. In the early days of pipe-line construction not much was known about coatings; for that reason, almost every conceivable material that was suspected of having protective qualities was used.

Within the last few years, worth-while progress has been made in the manufacture and application of coatings. The American Petroleum Institute, co-operating with the pipe-line industry and several coating manufacturers, began a study of this subject about 12 years ago. At about that time, Dr. Gordon Scott was employed to work on this subject, as well as on other phases of pipe-line corrosion. At the same time, the American Gas Association employed Dr. Scott Ewing for this purpose. Both of these experts in the field collaborated with the National Bureau of Standards.

One of the first undertakings of this group was to commence the study of the different types of coating materials and shields. Through the co-operation of coating manufacturers and pipe-line companies, sections of pipe were coated with the several materials in many widely scattered areas. These pipes were examined at intervals and detailed reports were made of their condition. The last and final inspection was made in 1940. At that time, the tests were 10 years old.

Space does not permit elaboration on the methods of making these examinations. It may be said, however, that a study of these reports will very clearly indicate the merits of the different

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors and not those of the Society.

classes of materials. In summing up the data from these reports, we may draw the following conclusions:

1 The material must adhere to the pipe.
2 It must be of high dielectric strength.
3 It must be impervious to moisture.
4 It must resist soil stress. This may be accomplished with the addition of a shield.
5 It must retain these qualities over a long period.
6 It must be practical to apply.
7 Its cost must be reasonable.

It is evident that the best of coatings would be of little value if improperly applied. For some time, it has been possible to have pipe coated in stationary plants, with the assurance that an almost perfect application will result. In these plants, pipes are coated up to very large diameters, and are lined with a coating if necessary.

Often, lines are built and then coated. Sometimes the pipe is coated in stationary plants and then hauled to the line. The joints are coated by hand methods. However, a large part of the lines constructed now are completely coated after the welding has been done. Not so long ago, this was done by hand methods, which procedure resulted in an excessive waste of material, a good application being almost impossible. During recent years, machines have been developed which travel on the pipe and apply the coating and shield very satisfactorily. These machines waste very little material and will coat several miles per day if it is necessary.

It is now common practice to test lines electrically for possible faults in the coating before laying them in the ditch. With the use of detectors and all other available equipment it is possible to apply protective coatings economically, with the assurance that practically a perfect application is being secured.

Nearly all of the foregoing has reference to prevention and precautions to be taken in the design of new lines or structures. However, it is on the older lines, built some years ago, that the effects of corrosion are most serious. It is on these lines that the engineer has been able to accomplish the most good.

Cathodic Protection

Theory of Cathodic Protection. The theory of cathodic protection is rather simple. It is assumed that corrosion is electrolytic in action. Because of galvanic differences in potential between small sections of the pipe wall, or due to changes in soil conditions, or both, small batteries are created. Sometimes, these soil changes may be some distance apart and still cause trouble. Now, if the pipe lies in contact with a soil that is a conductor of electricity, small currents will be generated. Loss of metal will occur at the points of discharge from the pipe. This is illustrated

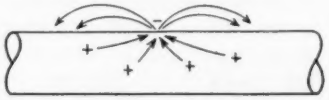

Fig. 1 Electrolytic Action on Pipe in Contact With Soil Which Acts as an Electrical Conductor

in Fig. 1. If the pipe is made cathodic to the surrounding soil, these currents can be prevented from leaving the pipe and there will be no loss of metal.

Application of Cathodic Protection. The application of this protection to a line or other structure is best illustrated by a rather simple electrical circuit, as shown in Fig. 2. As seen, the negative terminal of a source of direct current is connected to the pipe line or structure to be protected. The positive terminal is connected to a mass of scrap metal which is buried in the soil some distance from the line. In practice, we refer to the power supply as the "unit," the scrap metal as the "ground bed," and the connecting wire as the "ground-bed line." When the unit is turned on, current is forced from the ground bed, through the soil, and onto the pipe wall which carries it back to the unit.

Power Units. Naturally, the first and most important problem which arises in applying the protection is to secure a source of direct current. If commercial power lines are available, rectifiers can be used. Such units are now manufactured by several companies. They are available in almost any required size and come

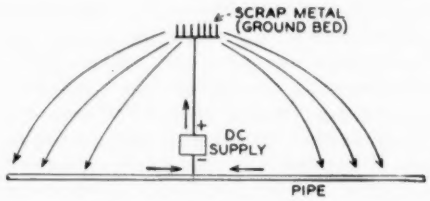

Fig. 2 Diagram Showing Application of Cathodic Protection to Pipe Line

complete, ready to put in use. Where power lines are not available, wind-driven units have been used with considerable success in some localities. Gas companies have used engine-driven units. In this case, fuel is taken from the pipe line. Some attempts have been made to use zinc anodes as the source of power. In this case, the driving force is the difference in potential between zinc and steel. This may be practical where the current requirements are comparatively small.

Ground Beds. The construction of the ground bed often becomes rather difficult. The purpose of this bed is to provide a path of low resistance for the current to enter the soil. It is necessary, therefore, to select the most favorable location. This is determined by securing the lowest soil resistance possible. The amount of metal to be buried, its distance from the pipe line, and the material to be used for the bed are factors which require consideration. Not only must the bed provide a low-resistance path, but it also must contain sufficient material to last for some time. Graphite or carbon anodes are available for this purpose and have been used to a considerable extent, especially when the bed is to be submerged in sea water.

Practical Application. In designing protection for a line or other structure, many factors must be considered. If engines are used, extensive protection will be secured from one unit. These units are not practical in small sizes. Wind units are limited in size and must be spaced on the line according to current requirements. Rectifiers may be large or small according to current requirements and location of power lines.

The amount of current necessary to protect a pipe line varies over a wide range. The factors that control this element are the size of the pipe, the condition of the soil surrounding the pipe, and the condition of the coating on the pipe, if any has been used. The last item is by far the most important factor. As an example of this, not long ago the author applied such protection to a line that had been coated by the most modern method. It took but 3 amperes to protect 20 miles of this line. Another line in the same type of soil and of the same size required 60 amperes per mile. This line is practically bare of any coating. The comparison is given as an example merely to show the variables encountered in the work.

Testing. As stated previously, the purpose of this system is to make the pipe cathodic to the soil. However, it must be more than just negative to stop the corrosion. By laboratory methods and by actual experience, we have found that the pipe must be at least 0.3 v negative to the soil to arrest the corrosion completely.

After a unit has been installed, the engineer measures the potential between the pipe and soil to determine its effectiveness. In

making these measurements, special equipment is used. First, it is necessary to have a contactor with the soil that will remain constant. A copper-sulphate plug is most commonly used for this purpose. The potential between this plug and the pipe is measured either with a high-resistance voltmeter or with a potentiometer.

If additional proof of the effectiveness is needed, coupons may be attached to the line. However, care must be exercised in doing this. Pilot coupons should also be placed unconnected in the same locality. In this instance, some time is required to get the information needed.

When the line is tested by means of the potential method, the readings may be plotted. When soil and coating conditions are uniform, a curve somewhat similar to the one shown in Fig. 3

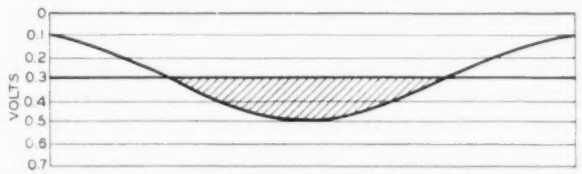

FIG. 3 TYPICAL CURVE DERIVED BY POTENTIAL METHOD WHEN SOIL AND PIPE-COATING CONDITIONS ARE UNIFORM

(The horizontal distance covered in this graph, as well as in Fig. 4, might be almost any distance. In some cases, it is as much as 16 miles and in other cases as little as 0.5 mile.)

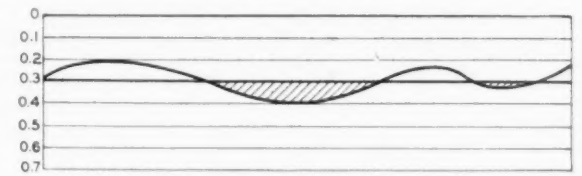

FIG. 4 VARIATIONS IN SOIL OR PIPE-COATING CONDITIONS PRODUCE A NONUNIFORM CURVE

would result. That part of the curve which shows a potential below the 0.3-v line would be protected. That part above this line but below the zero line would be protected but to a lesser extent. Any negative potential will prolong the life of the pipe.

It seldom occurs that a uniform curve, as shown in Fig. 3, is obtained. More often it will look something like the one shown in Fig. 4. These variations are due to changes in soil or coating condition.

Effectiveness of Cathodic Protection. Naturally, the question arises as to how effective this protection is. A few illustrations will demonstrate the value of this method. As far back as 10 years ago, the author applied this protection to two different lines that were in such bad condition and leak repairs were so frequent that their replacement was being considered. Cathodic protection was applied, with the result that both of these lines are still in service, no replacements having been necessary, and no further leaks have developed. Others have had similar experiences. On one section of the pipe line of an important company, a record of leak repairs was kept and plotted, as shown in Fig. 5. In 1936, cathodic protection was applied. The effectiveness of the method is shown by the curve obtained thereafter, as compared to what would have occurred had the protection not been applied. The prospective user may be assured that his corrosion losses will cease if this protection is properly applied.

Application to Structures Other Than Pipe Lines. Life can be prolonged on almost all underground or submerged metallic structures. Examples for treatment would be casings for water and oil wells, steel piling, underground cables, the inside walls of tanks, etc. Many large tank farms have applied this protection to the tank bottoms and connecting lines. Some work has been done in

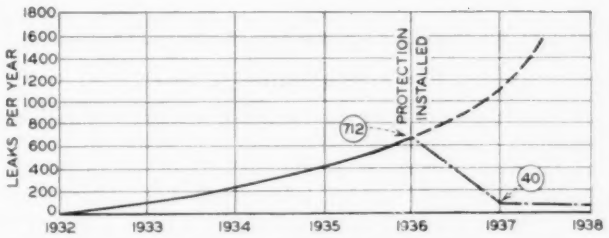

FIG. 5 CURVE SHOWING LEAK REPAIRS BEFORE AND AFTER CATHODIC PROTECTION WAS APPLIED

the protection of heat exchangers and condensers from corrosion. In at least one instance, the water jackets of an internal-combustion engine have been so protected.

Often, these structures are quite difficult to protect. As an example, one engineer applied this method of protection to a line consisting of 24 parallel pipes. In this case, large units were spaced but a few hundred feet apart, as against some miles apart on a pipe line.

CONCLUSION

It can no longer be said that the use of cathodic protection is an experiment. There are many hundreds of miles of lines now so protected and more are being added each year. Very few companies now replace corroded pipe, especially if any quantity is involved.

It is not likely that all corrosion can be eliminated. However, it is entirely incorrect to admit that corrosion is a necessary evil and must be tolerated. Probably most corrosion troubles can at least be mitigated.

Discussion

J. J. KING.[2] The subject of protection of buried metals, particularly pipe lines, is one of vital interest to those connected with the oil-and-gas industry. The same may be said for many other industries, though perhaps to a lesser degree because of the lesser amounts of buried lines involved. As operating pressures on oil, gas, and gasoline pipe lines are such that only steel pipe can be safely used in most cases, the problem of protecting such lines properly is becoming more important as additional miles of pipe are put underground.

Many different methods of coating pipe lines are employed in the oil-and-gas industry with such factors as the nature of the soil through which the line will pass, the degree of protection desired, and funds available for coating determining the type to be used. As brought out by the author, the use of cathodic protection for buried metals does not remove the necessity for coatings. As a matter of fact, it can safely be said that the more nearly perfect the coating, the more satisfactory the results from cathodic protection.

In the early days of the application of cathodic protection to pipe lines, scrap steel was almost universally used for ground beds, but in recent years carbon rods have been used as a substitute for scrap metal in some instances, with complete success. As scrap steel is not so available now as in previous years, it would have been timely for the author to mention the relative merits of metal and carbon rods for ground beds.

Recently, experimental work has been carried out in connection with the use of magnesium rods for the protection of pipe lines by burying cylindrical sections of this metal alongside of the pipe. In so far as the writer knows, very little has been published on

[2] Engineer, Producing Department, The Texas Company, Houston, Texas. Mem. A.S.M.E.

this work. If the author would care to comment upon the matter in the closure to his paper, his readers would be grateful.

Author's Closure

Fig. 2 of the paper illustrates the circuit that is used in cathodic protection. As shown, a mass of scrap metal is buried some distance from the pipe line to be protected. In the past it has been almost the universal custom to use scrap pipe for this ground bed. The exception has been when carbon, or graphite anodes were used.

The advantages of the scrap metal are (1) it generally has been readily available in the past; (2) its cost has been very small; (3) it is easily installed. The disadvantage of using this metal is that it has a very much shorter life than the carbon would have. Also, at this time, scrap metal may be more vital to our country than carbon.

As explained in the paper, one of the requirements of this ground bed is to provide a low-resistance path for the current to pass off into the soil. Often this is possible only by having a large anode surface in contact with the soil. In that case the cost of the carbon anode could possibly make its use prohibitive.

When the ground bed can be installed in sea water or in a soil of extremely low resistance, the use of carbon anodes would be preferable. Under such conditions, a small area would be required and a much longer life would result than with the use of metal.

It has been estimated that with the same current density on the discharge surface the graphite anode will last about 20 times as long as iron.

It is not probable that any set rule may be established as to which material should be used. There are so many factors involved that each installation should be engineered.

Some efforts have been made in the past to use a ground bed of such a material that an anodic condition would be created on the ground bed with the pipe line cathodic. This can be accomplished to a limited extent by the use of aluminum, zinc, or magnesium. In using this method, the circuit is the same as that shown in Fig. 2, with the exception that no generating unit is used.

It is easily seen that the driving force or difference in potential between the anode and the pipe line is very small. For that reason it is not possible to obtain any appreciable flow of current. Generally this current is measured in fractions of an ampere.

However, there is a place for this type of installation. Often it is necessary to protect a very limited area of small pipe or a larger but well-coated pipe. In such cases it is frequently not possible to install a power unit economically.

The advantage of the magnesium over zinc or aluminum for this purpose is that the difference in potential between this metal and the pipe is higher and the current flow is greater. Also, it is possible to protect a line completely with the magnesium, while the others only slow down the corrosion.

The disadvantage of this metal is that it is so unstable. It loses weight when buried in a soil and at a rapid rate whether connected in a circuit or not.

It is not probable that any of these metals will find a wide application since, at present, they are all on the critical list. It may be that other methods may be devised whereby the galvanic difference in potentials can be utilized.

The Application of Cathodic Protection for Corrosion Prevention

By R. J. SULLIVAN,[1] HOUSTON, TEXAS

The application of cathodic protection for the prevention of corrosion, either as the primary protective agent or in conjunction with external coatings, has been successfully and economically utilized on a variety of types of buried or submerged metal structures. This paper presents a short review of the subject of corrosion in general. However, it is devoted principally to the practical application of cathodic protection to numerous metallic structures. Sections are included covering the various types of equipment, the method of testing and keeping records in checking the operation of cathodic-protection installations, ground beds, preliminary survey methods, and illustrated descriptions of certain installations, such as pipe lines and oil-storage-tank farms.

A REVIEW of the published literature on corrosion will show that the result of a great amount of research, laboratory, and field work has been published on corrosion in general; that the effectiveness of pipe coatings has been tested in the field; and that cathodic protection has been found both practical and economical, either as a supplement to the coating, or as the primary protection for the submerged structures. Much has yet to be learned, however, about the proper application of cathodic protection.

The need for further research arises from the fact that the requirements for complete protection have not been agreed upon by all workers in this field, that better methods of predetermining the power requirements are needed, as well as further studies into the economics of the various types and combination of types of corrosion control. At the present time, the American Petroleum Institute (A.P.I.) is conducting an investigation on the effectiveness of resistance bonds.

Since we do not have the results of any research to report, this paper will be devoted to a short review of corrosion in general and methods of control. Principally, the discussion will deal with the equipment involved, various tests conducted, and records necessary to check the operation of cathodic protection units. Details of several electrolysis protection systems which are in service will also be included.

General Corrosion

Corrosion can be described as the disintegration or wearing away of metals by certain external agencies. This action can then be reclassified as caused by chemical or electrochemical attack or mechanical erosion. Often, corrosion and erosion operate together, promoting each other, and in practice may be difficult to distinguish. Evans (1)[2] of King's College, England, very aptly describes corrosion of a metal as "essentially the reverse process to the production of that metal from its ore. Metals occur in nature as oxide or sulphides; sometimes as normal or basic sulphates, chlorides, or carbonates which are reduced to the elementary condition by the smelting process; but when exposed in service, the metals sometimes return to the state of oxide sulphide, normal or basic sulphate, chloride or carbonate." Evans further states the interesting contrast "the study of metallurgy—the making of metals, appeals directly to a comparatively limited number of persons, but the study of corrosion—the unmaking of metals, has an interest for all who use metals, a far larger class."

Literature pertaining to corrosion indicates that, in general, there are two methods by which the disintegration of metals can take place. The first of these may be called direct chemical action and is typified by what happens when the metallic iron is exposed to the atmosphere at elevated temperatures. Under these circumstances, the iron reacts with and combines directly with the oxygen in the atmosphere to form the product which is commonly known as "mill scale," and which has essentially the same chemical composition as the naturally occuring iron ore called "magnetite." Other metals, when exposed to the same environment, behave in a similar manner to form a whole series of metallic oxides.

The second method by which disintegration of metal proceeds is called galvanic or electrochemical corrosion. This method differs from the first in that it is the result of the displacement of one element in one phase (usually in an aqueous solution) by another element originally present in another phase (in the solid form as a metal or alloy). Since this displacement of one element by another is invariably accompanied by a flow of electric current, this form of corrosion is broadly termed electrochemical. An excellent treatise on the accepted electrochemical theory of corrosion is presented by Speller (2).

Methods for Lessening and Preventing Corrosion

Various methods which have been successfully utilized in the protection of metals against corrosion, under a great variety of circumstances, are briefly as follows:

(*a*) Judicious selection of materials, which are immune to the corroding environment, is probably the most important means of preventing corrosion if the equipment involved is not too large. Various metals and alloys exhibit definite well-known properties when subjected to corrosive agents under certain conditions. Usually, the formation of a protective continuous film by interaction of the metallic substance with the corroding agent is the factor governing the suitability of the metal for the service. Because of this effect, lead is commonly used for exposure to sulphuric acid, the protective effect of the insoluble lead-sulphate coating keeping the attack low. Where the reaction of a considered material and a corroding agent is unknown, or questionable, corrosion tests can be made to judge their behavior, but these tests must be interpreted with caution, as aeration, temperature, movement of solution, etc., sometimes overbalance other factors. Kay and Worthington (3) offer a thorough discussion of the foregoing factors, and various alloy manufacturers (4) present tables listing materials and their suitability for different corroding agents. This method of preventing corrosion is widely used in condenser tubes, pipe, and the like. Special material is not usually adaptable for pipe lines because of the large tonnage

[1] Chief Engineer, Natural Gas and Gasoline Department, Humble Oil & Refining Company.

[2] Numbers in parentheses refer to the Bibliography.

Contributed by the Petroleum Division and presented at the Spring Meeting, Houston, Texas, March 23–25, 1942, of The American Society of Mechanical Engineers.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors and not those of the Society.

of steel involved, since a 1-mile section of 10-in. pipe line is composed of approximately 100 tons of steel.

(*b*) The mechanical application of impervious protective coatings such as paint and bituminous combinations, concrete mortar, and others, is very widely utilized and is ably discussed by Ewing (5), Larson (6), and Evans (1). An exhaustive series of pipe-coating tests has been conducted by the American Petroleum Institute for a period of 10 years, and the final report by Logan (7) has recently been published.

(*c*) The mechanical elimination of certain corroding constituents, i.e., oxygen and, to a lesser degree, carbon dioxide, have a pronounced effect on the corrosion of metals exposed to water. In many instances, the removal of these gases has successfully solved water-corrosion problems.

It is a well-established fact that oxygen in solutions combines with the hydrogen liberated as iron passes into solution during corrosion, thereby permitting the reaction to continue until the oxygen is used up. Oxygen also combines with the freshly dissolved iron to form an entirely new compound, an oxide of iron, and, in this manner, accelerates a concentration-cell pit, once it has started. Free carbon dioxide causes a lowered alkalinity in solutions, which increases the tendency for iron to pass into solution. For certain installations, where it is practical to remove these gases, corrosion can often be completely arrested. Both mechanical and chemical methods and combinations have been successful. Hammerschmidt (8) corrects the corrosive action of an engine cooling-water system by deaerating the water by means of natural gas which is passed countercurrent to the water through a novel contacting tower, after which the gas is utilized as engine fuel.

A notable example of mechanical deaeration has been described by Powell and Burns (9). A pipe line, designed to carry 4,000,000 gal per day of Mississippi River water a distance of 9 miles, suffered a rapid loss of capacity due to oxygen corrosion. The economic solution of this corrosion problem was obtained by a combination of physical and chemical deaeration. Ninety-five per cent of the dissolved oxygen was removed by passing the water through a slat-packed vacuum tower, operated at an absolute pressure of 1.5 in. Hg. The residual 5 per cent oxygen was removed by the addition of sodium sulphite, which combines with oxygen to form sodium sulphate. This deaeration plant has operated successfully since 1935.

(*d*) The chemical treatment of aqueous solutions by the addition of protective-film-forming agents, or the addition of oxygen-scavenging chemicals.

This subject is very broad, since each method of treatment is in itself a topic for lengthy discussion. The various types of waters encountered are susceptible to only certain chemical treatments. A judicious selection of chemicals is necessary since certain compounds will inhibit corrosion, but accelerate scaling, etc. The inhibitors generally used are sodium dichromate, sodium silicate, sodium hexametaphosphate, other phosphate salts of sodium, soda ash, caustic soda, lime, and various organic combinations. An example of this method is the treatment of boiler feedwater and cooling water for condensing and cooling systems with chemical inhibitors.

(*e*) The application of a counter electromotive force to reverse the natural electrochemical action taking place during the process of corrosion. This method is termed cathodic protection and will be discussed in the remainder of this paper.

Cathodic Protection

Cathodic protection is known as the process by means of which an electromotive force is applied to a corroding metallic structure in a manner such as to nullify or reverse the electrochemical reactions which take place during the natural corrosion of the metal. This method consists of making the structural metal the electrode which receives current from the corroding solution in an electrochemical cell. The structural-metal electrode in this case is called the cathode in a protective system. The other electrode from which the current enters the solution is called the anode. The cathode and the anode are connected externally by a suitable metallic circuit. When the current is supplied by a generator or a battery in the external circuit, the arrangement is called one of impressed-voltage cathodic protection. If the current is supplied by the natural galvanic action of two dissimilar metals used for anode and cathode, the arrangement is called galvanic cathodic protection. In both cases, the protection of the cathode structure is at the expense of the anode metal which corrodes in proportion to the protective current produced.

Galvanic cathodic protection has been used in protecting pipe lines, as well as small structures. A few years ago, a group of engineers experimented with various anode materials. However, at present the scarcity of suitable metals prohibits the use of this type of cathodic protection, and consequently will not be discussed.

The use of cathodic protection of underground structures probably developed through the practice of bonding these structures to the return circuits of electric railways for the prevention of stray-current electrolysis. It was soon observed that, in addition to stopping the leaks, caused by stray currents, there was a lessening of natural corrosion in the vicinity of the bonds. This suggested the possibility of preventing corrosion by impressing a negative potential on the pipe.

The potential difference between metallic structures and the surrounding solution necessary for protection has been reported by several investigators (10, 11, 12, 13, 14), and has been found to vary from 0.8 to 1 v when measured with a copper-sulphate electrode.

The amount of current entering the surface of a bare-metal structure, or the current density necessary to produce a protective potential depends upon the nature of the solution in contact with the metal. Laboratory investigators (15, 16, 12) have indicated that the required current density varies from 1.2 to over 30 ma per sq ft for various solutions. For well-coated lines or structures, the current density will be very small, since it is only necessary to protect the "holidays" or small uncoated areas.

The question of the possible damage done by a cathodic-protection installation to an adjacent nonprotected metallic structure and the proper method of preventing any damage have never been agreed upon. However, at the present time, the A.P.I. is conducting a research on this problem. Since most of the pipe-line companies are participating in the investigation, a satisfactory solution is likely to be obtained.

Results Obtained With Cathodic Protection

Hough (17) reviewed the results obtained by ten pipe-line companies at a meeting of the American Gas Association in Houston, in 1940. Nealy (18) and Miller (19) presented papers at the 1941 mid-year meeting of the A.P.I. on the application of cathodic protection to refinery equipment. These papers could be summarized as follows: That positive beneficial results were obtained; that there was no serious difficulty in maintaining cathodic protection; that the cost of applying cathodic protection is less than reconditioning and/or repairing the equipment; and that there is yet much to be learned about the proper application to secure the necessary protection with a minimum investment and power consumption.

Equipment

The essential equipment for constructing a cathodic-protection installation, as mentioned, are the anode (or ground bed), a source

of direct current, and the necessary electrical connections between the ground bed, source of direct current, and the cathode or the structure being protected. The selection of proper material is a problem similar to that of other engineering projects. There is an economic medium between the first cost and operating cost which should govern the selection of the equipment. Some very helpful information on the equipment available has been published by Ewing (5) and others (20).

Fig. 1 illustrates a typical cathodic-protection installation.

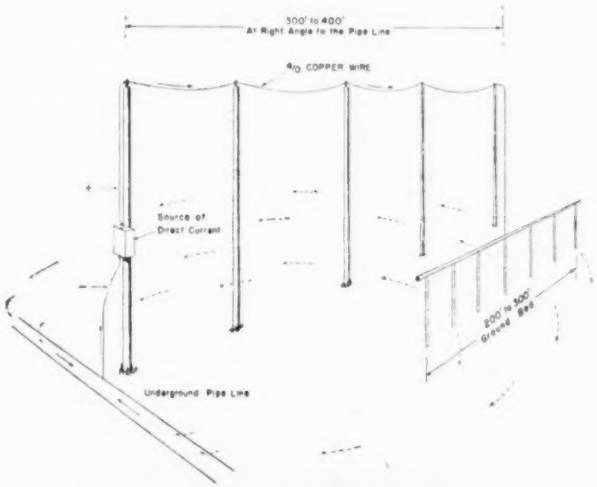

FIG. 1 TYPICAL CATHODIC-PROTECTION INSTALLATION

Since the direct-current voltage is generally low (less than 15 v), it is obvious that large conductors must be used. Conductor lines of copper are generally used; however, in some instances, old steel cables have been utilized.

The anode (or ground bed) should preferably have low resistance, sufficient volume to last several years, and current spread.

To secure low resistance, it is necessary to locate the ground bed in a low-resistance soil, and also to provide a sufficiently large area of exposed anode surface. At times it is also necessary to add salt and sometimes water to the ground-bed soil to lower the resistance. The life of the bed can be estimated from the weight of metal installed, its electrochemical equivalent, the amount of current flowing, and an assumed efficiency. The efficiency of ground beds under different arrangements has been reported by Rogers (21) and McAnneny (22). For the best distribution of current over the entire structure, it is advisable to have ground beds distributed at several points along or around the structure, since it takes a definite amount of current to protect a unit area; if the current is concentrated more than is necessary, the excess is wasted. An exception would be in the case of a well-coated line or structure where it would probably be more economical to install a small number of large units, as the resistance offered by the protective coating prevents high current densities in the vicinity of the ground bed. The high metal-to-ground potential does not indicate a waste of power. It should be further stated that conditions, such as cheap power, size of the structure, and the like, might make it more economical to install large units even on bare structures.

The most commonly used material for ground beds is junk pipe, old castings, scrap iron or steel, and carbon or graphite rods. Some experimental chemical ground beds have been reported by McAnneny (22). While chemical ground beds have not been used to date, the present scarcity of junk pipe and other suitable materials will encourage their development.

The majority of ground-bed installations consist of junk pipe because it is reasonably cheap, easy to install, and provides a better current distribution per pound of metal than other forms of scrap iron. This pipe is installed either vertically or horizontally, depending upon such conditions as the space available, type of soil, and depth of low-resistance soil. The location of the ground bed will be influenced by the size and surface condition of the structure being protected.

The requirements of an apparatus for producing a suitable direct current are (*a*) reliability, so as to require little attention; (*b*) ability to produce large direct currents at low voltages; and (*c*) economy of operation. Four methods of producing direct current are in general use, i.e., the alternating-current rectifier, the motor generator, the gas-engine-driven generator, and wind-driven generator.

The alternating-current rectifier is the most widely used method for providing a source of direct current where the output is less than 3000 w. The advantages of the rectifier are simplicity of installation; low maintenance, since there are no moving parts (except the cooling fan in some models); over-all efficiency of between 55 and 65 per cent, depending upon the size and the source of alternating-current power available; and initial cost, which is comparable with the motor generator set.

Motor generator sets may be used if a source of alternating-current power is available as with the rectifier, and are generally used where the output is above 3000 w. The over-all efficiency is approximately 65 per cent. The current of a motor generator is constant and may be varied to any desired output. This set must have some attention because of the moving parts and is, therefore, more suited for tank-farm and station-protection installations than for use on pipe lines and isolated areas.

Gas-engine-driven generator sets of various sizes are being manufactured. Such units produce a constant source of direct current, but because of the inherent nature of the gas engine, they require frequent servicing and repair.

The windmill or wind-driven generator, while picturesque, is not a very dependable source of direct current, since the output of the generator depends upon power derived from the wind; thus, during a calm period, no current is generated. These units are available in sizes from 20 to 2000 w, and their principal use is in isolated locations where there is sufficient wind for their operation.

The majority of installations for pipe lines, tank farms, and station equipment utilize rectifiers, with the motor generator and gas-engine generator as second and third choice, respectively. The wind-driven generator is seldom used except in isolated places. In some cases, two wind-driven generator units are installed; one to protect the pipe line, and the other to charge a battery which will discharge to the electrolysis system during periods of no wind.

Ewing (5) and others (21) have presented analytical methods of determining the number of units and the size most suitable for protecting pipe lines and similar structures, by taking into consideration the condition of the coating and the soil resistivity, which is known or determined experimentally.

Another method for determining the current and number of units required for protecting well-coated lines has been to install a temporary unit for experimental purposes. The installation consists of a ground bed of four or five 4-in. carbon rods or four 10-ft pieces of 4-in. or 6-in. pipe in a shallow well-salted trench about 100 ft from the pipe line. For a source of power, either six or eight regular storage batteries are used. The pipe line, batteries, and ground bed are connected with No. 2 insulated copper wire. By the proper arrangement of the batteries in series and parallel, it is possible to obtain a suitable unit output.

After this equipment has been installed and adjusted, pipe-to-ground potentials are taken in each direction to determine how much pipe is being protected. At each end of the section where

the pipe-to-ground potential is 0.8 v (referred to a copper-sulphate electrode), the current flowing is determined. The sum of these readings deducted from the total drained from the line will indicate the amount of current required to protect that particular section. By measuring the length of line protected, the current per mile necessary for protection can be determined. From these data, the size and location of the units can be made.

The procedure for determining the current required for protecting poorly coated or bare lines is the same as that just outlined, except a larger ground bed is usually installed, and a welding-machine or similar direct-current generator is required in place of the storage batteries.

Cathodic-Protection Methods Employed by Author's Company

The natural-gas department of the author's company has applied cathodic protection on approximately 120 miles of 10-in. line, and on another 60 miles of line, ranging in size from 3 to 8 in. Some of these lines pass through developed suburban territory, and at places they cross and are parallel to other pipe lines, oil-field, and refinery equipment.

Cathodic protection was installed as a preventive measure, there having been no leaks to date. The oldest section of line was laid about 10 years ago and was provided with a protective coating of a cold asphalt application without a wrapper. The other lines are all 5 years old or less and were protected from external corrosion by the application of a primer, two coats of petroleum asphalt enamel, and an asbestos-felt wrapper. The exception to this procedure was river or swamp crossings, at which areas an additional coat of enamel and Osnaburg was also applied.

For cathodic protection on these lines, it was found most practical to locate the units at points within ready access to electric power and most suitable for ground beds.

The lines mentioned are protected with eight units, four of which supply some protection to the Humble Pipe Line Company. The lines of the Humble Pipe Line Company are new and have coatings equal to the natural gas department lines.

It has been assumed that the metal is protected when the pipe line is 0.8 v negative to the soil, the pipe-to-ground potentials being determined by means of a potentiometer and a copper-sulphate electrode. Some coupons were attached to the pipe and, to date, no pitting has been observed.

The following procedure has been adopted for routine tests. When the first cathodic-protection unit was installed, a few complete pipe-to-ground surveys of the protected area were made and were found to have the same trend each time. Then the practice of making a complete survey was dropped, and only a few readings are made at the present time at permanent test locations.

After a new unit is installed a pipe-to-ground-potential survey is made to determine the limits of protection from the unit or the point of lowest potential between the unit and adjacent units.

Permanent test stations are then made at convenient points. These are located at or near the end of the section protected and near the rectifier unit. At each of these locations, a permanent weatherproof insulated copper wire is soldered onto the pipe, after which the other end is made fast to a fencepost or the concrete pipe-line marker at the side of the road. Potential readings are made between this wire and a copper-sulphate electrode which is placed over the pipe line and 1 ft away from the lead-wire connection. Potentials are determined with a Rhodes potentiometer.

Routine checks over the whole system are made each month by measuring the pipe-to-ground potentials at the permanent test station, and by checking the rectified voltage and current. Field data are recorded in a civil-engineer's notebook as it is taken, after which the original sheets are removed and made into a permanent file. From these data, the system potential map and also the unit data sheets are kept up to date. The potential map is a map of the entire system which is provided with blank spaces near each test station and a unit for recording the measured potentials and unit output. The unit data sheets contain information on unit output in volts and the current drained from each line; the ground-bed resistance; the power bill for the month, and remarks. This potential map and the unit data sheets afford a quick check of the entire system with reference to potentials and condition of equipment. The system can be checked by one operator in less than 3 days.

Cathodic Protection of an Oil-Storage-Tank Farm

The Humble Pipe Line Company has applied cathodic protection on a large oil-storage-tank farm and pump station in the Gulf Coast area, where the soil is fairly corrosive.

This farm consists of 62 storage tanks, 115 ft diam, with the auxiliary connecting lines, pumps, and station equipment. About 28 miles of buried pipe are involved in sizes varying from 2-in. to 16-in., the majority being 8-, 10-, and 12-in-diam pipe. In addition, various large-diameter incoming and outgoing lines are involved. Some of the lines have been coated and others are bare.

A number of tank bottoms have required replacement due to a combination of internal and external corrosion. Pit-hole leaks caused by external corrosion were also occurring on the oil lines at such a rate that maintenance required the expenditure of several thousand dollars a year. A cathodic-protection system was, therefore, installed and placed in operation in May, 1941.

The equipment consisted of a total of nine copper-oxide recti-

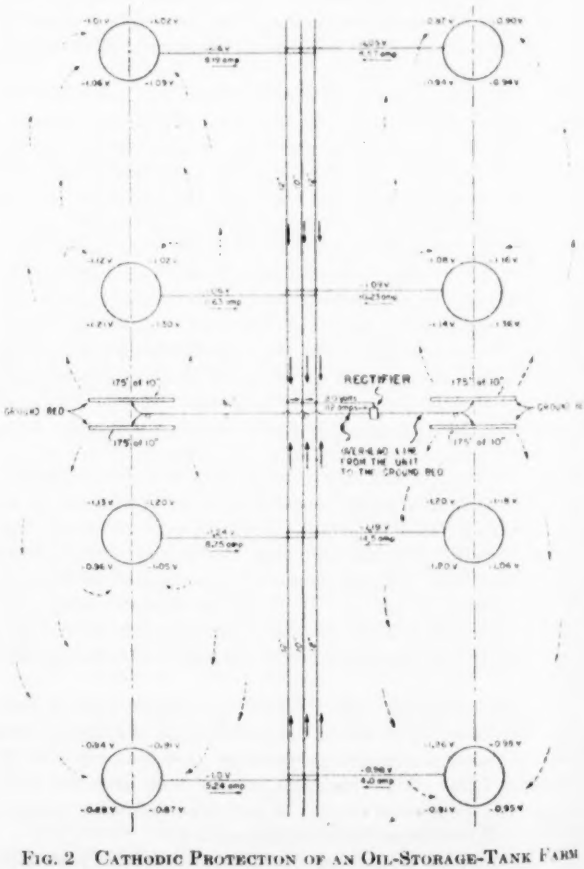

Fig. 2 Cathodic Protection of an Oil-Storage-Tank Farm

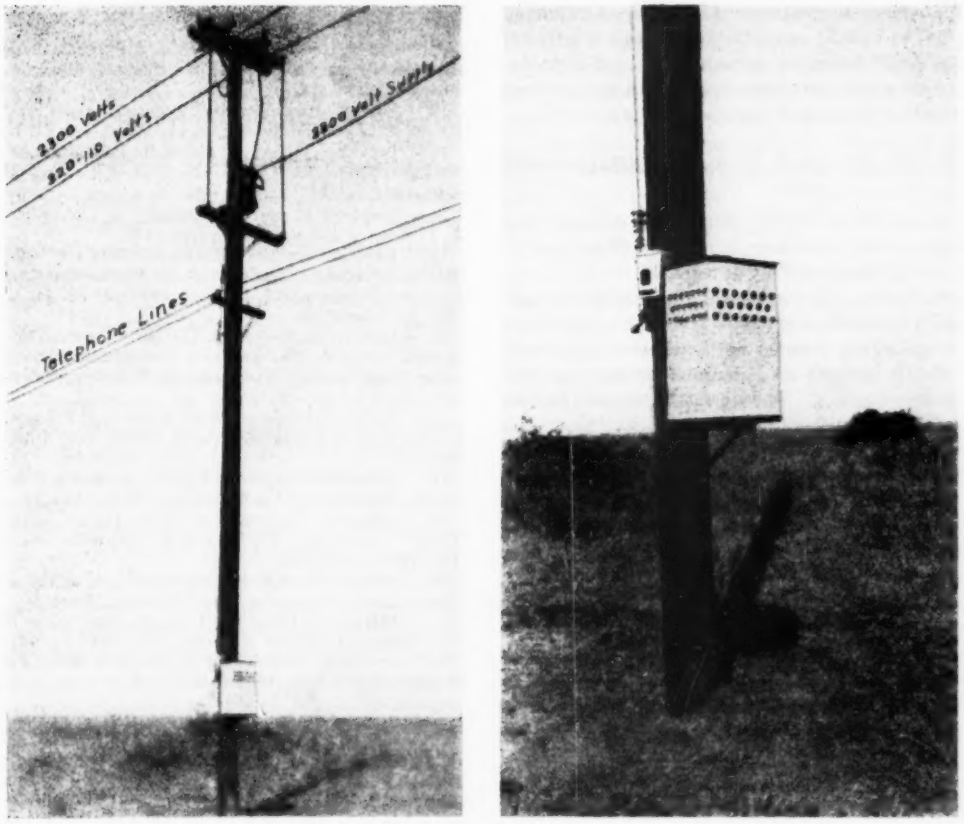

FIG. 3.—CATHODIC-PROTECTION INSTALLATION USING SMALL CLOSELY SPACED UNITS WITH POWER AND TELEPHONE LINES ON SAME POLES

fiers with the necessary ground beds, alternating-current power lines and transformers, and direct-current drainage and feeder lines. Seven rectifiers were 10-v, 120-a units, manufactured by Westinghouse, and two units were $10^1/_2$ v, 130 a, manufactured by General Electric.

The arrangement of the rectifiers and ground beds for one of the units with respect to the tanks and lines is illustrated in Fig. 2; this unit is typical for the combined system. It was possible in most cases to achieve a symmetrical arrangement of the rectifiers and ground beds so that one unit was centrally located with respect to eight tanks and the pipe lines serving them.

The ground-bed arrangement, shown in Fig. 2, has been particularly effective and consists of approximately 20,000 lb of junk pipe of 8, 10, and 12 in. diam, which is expected to serve for about 10 years. The ground-bed pipe is buried horizontally about 5 ft deep. Four sections of pipe are used in each dual ground bed which is arranged as shown with parallel sections 20 ft apart. A 6-in. riser pipe is welded into the middle of each section to which are connected the positive terminals of the unit. The risers extend above the ground and are left open so that water can be poured in if necessary to lower the resistance. This represents an external resistance of $^1/_{18}$ ohm, and in no case was the resistance greater than $^1/_{10}$ ohm for a ground bed of this type. Additional metal is now being added to three less efficiently arranged ground beds to improve their configuration.

Results achieved in eliminating or reducing corrosion cannot be accurately estimated at present because of the short period of time the system has been in operation. A survey is being made, however, which will indicate the metal-to-earth potential of the various structures, and of the amount of current being collected by the various portions of the tank and pipe-line system which will theoretically indicate the degree of protection.

The metal-to-earth potential values are shown in Fig. 2 for four points around each of the tanks, as well as the potentials of the pipe lines leading to the tanks, and the current being drained from each tank. The lowest potential value was found to be 0.87 v which indicates that all structures in this portion of the tank farm are receiving adequate protection. It may be noted that both potential and current drainage are somewhat affected by proximity of the structures to the ground beds. In the case of one tank, satisfactory potentials are obtained with a drainage of 4 a. The drainage from another tank is $14^1/_2$ a, but the negative potentials of the metal to earth are unnecessarily high. This suggests that a more even distribution of potential at a lower power consumption might have been obtained with a yet wider distribution of the ground-bed anodes, or by a system of negative connections which would permit the introduction of resistances into the drainage connections to structures close to the ground beds. In this case, however, it is doubtful whether the saving in power from such changes would justify the cost of making them.

The best measure of the effectiveness of such a system of protection is the stoppage of failures due to corrosion. While the time the system has been in operation is too short for positive conclusions to be drawn, there has been an apparent reduction in the number of failures. From the beginning of 1938, through the third quarter of 1941, leaks occurred on the lines at this station at the average rate of six a month. During the last quarter of 1941, only three leaks occurred, or an average of one a month. A much longer time will naturally be required to observe any change in rate of failure of the tank bottoms.

It is believed that this system of protection, which cost the company about $13,000 to install, and which involves a yearly expenditure of about $3000 for power, maintenance, and depreciation, will prove to be much more economical than the previous maintenance methods, consisting of repairs and renewals.

Cathodic Protection on Large Bare or Poorly Coated Lines

A very practical and unique method of applying cathodic protection by one large pipe-line company in the Gulf Coast area on large and poorly coated lines is worthy of mention.

The telephone-line poles, which are located alongside the pipe line, were changed by replacing every third pole with a power pole on which was strung a 2300-v primary line and a 110-v secondary line. The pipe line is utilized as a common return for both primary and secondary circuits. The small rectifiers are located on these power poles and utilize the 110-v circuit. About ten rectifiers and ground beds are used per mile of pipe. By a judicious selection of material, it was possible to make a very flexible and economical installation.

The economy of the purchased power for such an installation is well illustrated by the following readings which were taken on a section of a coated line, part of which was protected with the small units just described, and part protected with a large unit. The large unit protected 2.6 miles of line with a direct-current output of 20 v and 40 a, or 800 w. On an equal and adjacent length of line, 26 small units had an average direct-current output of 30 v and 2.7 a, or 210 w. Views of this installation are shown in Fig. 3.

Conclusion

It is concluded that cathodic protection will prove the most economical means of preventing external corrosion for pipe lines and similar structures, and we are using it in addition to external protective coatings. At present, the author's company has protection on several hundred miles of pipe lines, part of which are in salt-water marshes and bays, as well as on oil-storage-tank farms. In closing, it should be restated that a great deal is yet to be learned about the proper application of this form of protection.

Acknowledgment

The writer wishes to thank the Humble Oil & Refining Company, for permission to publish the data contained in this paper, and Mr. E. O. Staffel and Mr. R. A. Brannon for their help in preparing it.

Discussion

R. W. Warner.[3] Corrosion is a relentless enemy and one that knows no quarter. It is possible that fundamentally all metals are subject to this process of reverting back to their original state unless prevented by some natural or man-applied means. Our most useful metal, iron, is particularly subject to the ravages of corrosion especially when combined with other metals or compounds for the purpose of improving its commercial characteristics.

The author has presented an exceedingly interesting paper on some of the methods used by his company in combating corrosion of pipe lines and storage tanks. General acceptance of the electrolytic theory of corrosion at once suggested the feasibility of an electrolytic preventative. As he points out this is relatively simple in theory but more difficult in application because of the tremendous variety of conditions in the field.

Electrolytic corrosion is accompanied by the flow of electrical current in response to natural potentials which become established between a metal and a surrounding electrolyte which may be soil, a salt-brine solution, plain water, or any other medium capable of conducting electric current. The arrangement becomes a natural electrolytic cell. An ordinary dry battery is a common example of such a cell in commercial form.

The amount of voltage developed in such a natural battery is not large, in fact usually well under one volt. It depends upon a wide variety of conditions, such as the kind of metal present, the purity of the metal, the presence of unrelieved strains in the metal, the temperature gradient between parts of the metal, and upon the electrolyte itself. In the case of pipe lines buried in the earth this voltage also depends upon the chemical characteristics of the soil. Even though only a small voltage is developed, the natural battery thus formed is short-circuited through the body of the metal itself so that an electric current flows constantly. The amount of this current also is small but the cumulative action over a period of months or years is enormous.

[3] Professor of Electrical Engineering, The University of Texas, Austin, Texas.

Decomposition occurs only at points where the current leaves the metal. Wherever it enters no harm is done. The metal or electrode from which current flows into an electrolyte is known as the anode while that by means of which the same current leaves the electrolyte is called the cathode. Corrosion does not take place at the cathode. In order, then, to prevent corrosion which takes place as a result of the natural potentials mentioned it is necessary only to prevent the flow of the electric current, or to be on the safe side, to force it to flow in the opposite direction. The metal it is desired to protect is thus forced to become a cathode. Some other piece of metal, the corrosion of which will be harmless, is placed in the electric circuit as the anode. All the corrosion is centered at the anode. This, in the case of a pipe line or storage tank to be protected, is the ground bed. The best method of application and the amount of protective current required depend entirely upon the local conditions; and the author has given the upper and lower limits of the current needed.

It has been observed in many cases that a film or coating is deposited on metals that are being protected as cathodes. This film of itself possesses a certain protective value against corrosion just as do paint, asphalt, and other coatings. Its composition depends upon the electrolyte and the material of the anode. With metals in a salt-brine solution a chunk of zinc may effectively be used as the anode. A protective film consisting of a complex compound of zinc, oxygen, and chlorine is formed on the surface of the cathode. Its presence is a visual indication that the protective scheme is functioning. The film is soluble but will furnish complete protection for some time after the protective current is removed. To form such a film on steel, a current density of approximately 5 ma per sq ft of surface to be protected is necessary. This value falls well within the limits of current density given by the author for the protection of pipe lines and storage tanks.

When cathodic protection is applied to metals buried in the earth a similar coating is formed on the metal. It consists of compounds taken from the soil and deposited electrolytically upon the metal; without doubt it possesses protective characteristics. It would be interesting to know how long this coating would furnish protection if the current were to be removed. This might materially affect the cost of protection.

It is believed that the nonrusting characteristic of stainless steel is due to the presence of a natural protective film perhaps only one molecule in thickness. It is possible that an exhaustive study of protective films in general would furnish valuable information about corrosion.

Pipe lines buried in the earth frequently lie in the path of natural stray earth currents. Not a great deal is known about these wandering currents—as to what causes them, where they originate, or where they end—other than that they circulate constantly through the surface of the earth in widely varying amounts, sometimes in one direction and then reversing and flowing in the opposite direction. They undoubtedly follow pipe lines and contribute to their decomposition. A study of these natural currents would no doubt yield valuable and interesting information.

The author mentions the economic phase of cathodic protection and while the economics are certainly in favor of protection it would be extremely interesting to know more about the amount of annual savings that can be expected. This would form excellent material for a subsequent paper. Also, it would be interesting to know about the effectiveness of this method of protection, after a period of perhaps ten years of operation.

Effect of Variable Viscosity on Boundary Layers, With a Discussion of Drag Measurements

By J. G. BRAINERD,[1] PHILADELPHIA, PA., AND H. W. EMMONS,[2] CAMBRIDGE, MASS.

This work extends a previously reported investigation of the boundary-layer problem associated with the steady laminar flow of a perfect gas along a thin flat insulated plate. In the earlier study the viscosity was assumed constant and the distributions of velocity and temperature were obtained for a wide range of conditions. Part I of the present paper shows, for Prandtl number 0.733 (air) and Mach number of the undisturbed stream 2, the velocity and temperature distributions in the boundary layer under various assumed viscosity variations. Part II gives the distributions for various Prandtl numbers and Mach numbers, assuming the same viscosity functions as used by von Kármán and Tsien. Part III is devoted to a discussion of the method of interpretation of traverse tests of the efficiency and flow coefficients of nozzles or other passages. The results of Part I show that the variation of viscosity with temperature does not alter the equilibrium temperature of the plate, and hence the reading of a plate thermometer. This result is extended in Part II where it is shown that θ at the plate wall is equal to the same quantity when μ is taken constant to within 1 per cent in all cases studied. Furthermore, $\varphi U'$ at the plate wall does not vary greatly, so that the drag coefficient C_D is equal to $1.28/(\mathrm{Re})^{1/2}$ to within 5 per cent for most of the cases investigated. In Part III a passage efficiency as usually calculated is found to be subject to two errors, one of which reduces and the other of which increases the test result. The net effect is to cause the standard traverse test to give a conservative estimate of the efficiency. The flow coefficient as determined by traverse tests is somewhat higher than the correct one.

Nomenclature

a, a_1 = see note on subscripts at the end of the list
$b = (\gamma - 1)M_1^2$ = compressibility number
B = breadth of plate
c_v = constant-volume specific heat
c_p = constant-pressure specific heat
C_d, C_s = see Table 3
C_D = drag coefficient
E = internal energy per unit mass
$\boldsymbol{F}$ = vector body force per unit mass
h = enthalpy
k = thermal conductivity
L = length of plate
M_1 = Mach number of undisturbed stream = u_1/(acoustic velocity in undisturbed stream)
p = pressure
$\mathrm{Pr} = c_p\mu_1/k_1$ = Prandtl number
$\mathrm{Re} = u_1L\rho_1/\mu_1$ = Reynolds number
R = gas constant
s = entropy
t = time
T = absolute temperature
u = velocity component in X direction, along plate
$U = u/u_1$ = dimensionless velocity along plate
v = velocity component in Y direction, perpendicular to plate
$\boldsymbol{v}$ = vector velocity with rectangular components u, v, w
$V = v(x/\nu_1u_1)^{1/2}$ = dimensionless variable containing velocity perpendicular to plate
X, Y, Z = rectangular co-ordinate axes
x, y, z = rectangular co-ordinates of a point
$\gamma = c_p/c_v$
δ_u = thickness of velocity boundary layer
δ_T = thickness of temperature boundary layer
ϵ, ϵ_1, ϵ_2 see Table 3
$\eta = y(u_1/\nu_1x)^{1/2}$ = dimensionless variable, proportional to distance from plate wall at a fixed x
$\theta = T/T_1$
μ = absolute viscosity
$\nu = \mu/\rho$ = kinematic viscosity
$\xi = \eta U - 2V$ = velocity variable
ρ = mass density
τ = shear stress
φ_B, φ_C, φ_K, φ_S see Equation [16]
$\boldsymbol{\psi}$ = stress dyadic

Subscripts and primes: Subscripts 0 and 1 denote conditions at the plate wall ($\eta = 0$) and in the undisturbed stream, respectively; subscript a indicates an isentropic stagnation condition and a_1 the isentropic stagnation condition in the undisturbed stream. A prime denotes differentiation with respect to η.

The General Problem

In a previous paper (1),[3] assuming μ and k constant, the velocity and temperature distributions in the boundary layer adjacent to a thin flat insulated plate lying parallel to the undisturbed direction of a gas stream were given for a wide range of conditions. The present investigation extends those results by taking into account the dependence of μ and k on T. For the sake of brevity the mathematical basis of this investigation will be outlined in compact form; greater detail for the more-or-less parallel theory of the first study is given in the earlier report (1).

Presented at the National Meeting of the Applied Mechanics Division, Philadelphia, Pa., June 20–21, 1941, of The American Society of Mechanical Engineers.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until April 10, 1942, for publication at a later date. Discussion received after the closing date will be returned.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

[3] Numbers in parentheses refer to the Bibliography.

The basic equations are, in the Gibbs vector notation

$$\nabla\cdot(\rho\boldsymbol{v}) + \partial\rho/\partial t = 0 \quad [1]$$

$$\rho\partial\boldsymbol{v}/\partial t + \rho\boldsymbol{v}\cdot\nabla\boldsymbol{v} = \rho\boldsymbol{F} - \nabla\cdot\psi = \rho\boldsymbol{F} - \nabla p - (^2/_3)\nabla\cdot(\mu\nabla\cdot\boldsymbol{v}) + \nabla\cdot(\mu\Phi) \quad [2]$$

where

$$\Phi = \nabla\boldsymbol{v} + (\nabla\boldsymbol{v})_{\text{conjugate}}$$

$$\nabla\cdot(E\rho\boldsymbol{v}) = (\psi\,\nabla)\cdot\boldsymbol{v} + \nabla\cdot(k\nabla T) \quad [3]$$

$$p = RT \text{ and } E = c_v T \text{ (perfect gas)} \quad [4a,b]$$

For a gas streaming in the $+X$ direction along a thin flat insulated plate, of indefinite extent in the $+X$ and $\pm Z$ directions and with the Z axis for its edge, these equations state that in the boundary layer the following relations hold closely under the conditions and assumptions previously used (1), and with $\mu = \mu_1\varphi$; $k = k_1\varphi$ (see Part I)

$$\theta(\xi' - U) = \theta'\xi \quad [5]$$

$$\xi + \frac{2\theta}{U'}\frac{d}{d\eta}(\varphi U') = 0 \quad [6]$$

$$\xi' - U + \frac{2}{\Pr}\frac{d}{d\eta}(\varphi\theta') + 2b\theta U'^2 = 0 \quad [7]$$

subject to the boundary conditions $U = V = \theta' = 0$ when $\eta = 0$ (i.e., when $y = 0$) and $U = \theta = 1$ when $\eta \to \infty$ (i.e., when $y \to \infty$).

The equations yield

$$\theta = -\frac{1}{2}U/\frac{d}{d\eta}\left[\varphi\frac{d}{d\eta}\log(\varphi U')\right] \quad [8]$$

$$\xi = -\frac{2\theta}{U'}\frac{d}{d\eta}(\varphi U') \quad [9]$$

$$\theta'' - (\Pr U''/U')\theta' + b\Pr U'^2 + \theta'(1-\Pr)\,d\log\varphi/d\eta = 0 \quad [10]$$

Equation [8] gives θ in terms of μ and U; Equation [9] then yields ξ (hence V) in terms of μ and U. Equation [10] is a different form of the relationship between θ and μ, U. For the special case $\Pr = 1$ which has been studied by von Kármán and Tsien (2), the term containing μ drops out and after some manipulations there is obtained

$$2(\theta - 1) = b(1 - U^2) \quad [11]$$

At the plate wall, where $U = 0$, the temperature ratio $\theta_0 = (b/2) + 1$.

Now (1)

$$b = (\gamma - 1)M_1^2 = 2(\theta_{a1} - 1) \quad [12]$$

hence, for $\Pr = 1$

$$(\theta - 1)/(\theta_{a1} - 1) = 1 - U^2 = (\theta - 1)/(b/2) \quad [13]$$

The last quantity is used as ordinate on some of the curves of Parts I and II, although $\Pr \neq 1$ for any of them.

The drag coefficient for a thin plate (two sides) of length L in the X direction and breadth B in the Z direction, assuming that L and B are not too small and that end effects may be neglected, is

$$C_D = 4\varphi_0 U_0'/(\mathrm{Re})^{1/2} \quad [14]$$

For the case of constant viscosity, Equations [8], [9], [10], and [14] reduce to

$$\left.\begin{aligned} &\theta(\xi' - U) = \theta' \\ &2\theta U'' + \xi U' = 0 \\ &(2/\Pr)\theta'' + \xi' - U + 2bU'^2 = 0 \\ &C_D = 4U_0'/(\mathrm{Re})^{1/2} \end{aligned}\right\} \quad [15]$$

which are the equations on which the previous study was based (1).

I—VARIOUS TYPES OF VISCOSITY VARIATION

There are numerous approximations for the dependence of μ on T. To determine the relative effect, on θ, θ', U, U', and V, of taking different μ variations, the particular case $\Pr = 0.733$ (air) and $b = 1.6$ (Mach number of undisturbed stream 2) was studied for 6 μ's

$$\left.\begin{aligned} &\mu = \mu_1 \quad = \mu_1\varphi_C \\ &\mu = \mu_1\theta^{1/2} \quad = \mu_1\varphi_B \\ &\mu = \mu_1\theta^{0.768} = \mu_1\varphi_K \\ &\mu = \mu_1\left(\frac{T}{T_1}\right)^{3/2}\frac{T_1 + 114}{T + 114} = \mu_1\varphi_S \\ &T_1 = 175, 273, 375\ \mathrm{C} \end{aligned}\right\} \quad [16]$$

where μ_1 is the value of μ in the undisturbed stream, and φ denotes the temperature function μ/μ_1. Thus φ_C is 1, $\varphi_B = \theta^{1/2}$ gives[4] μ/μ_1 as required by elementary kinetic theory, $\varphi_K = \theta^{0.768}$ is μ/μ_1 as used[5] by von Kármán and Tsien, φ_{S175} is μ/μ_1 as required[6] by the Sutherland formula (4) with $T_1 = 175$ C, and φ_{S273} and φ_{S375} are similar. Fig. 1 shows the variations of the φ's with θ.

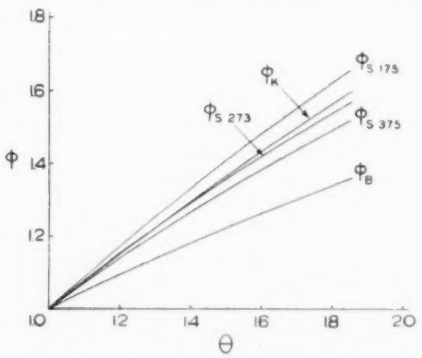

FIG. 1 VARIATION OF φ'S WITH θ ($\mu = \mu_1\varphi$ AND $k = k_1\varphi$; THE DIFFERENT φ'S ARE DEFINED IN EQUATIONS [16])

The kinetic theory of interacting spherical molecules indicates that the Prandtl number varies only slightly with the temperature. Experimental results on this point are meager but tend to confirm the theoretical prediction and suggest the empirical rule that Pr is constant in any range of the temperature in which c_p is constant. The specific heat c_p does not vary rapidly with the temperature and will be assumed constant in this paper. From the definition of Pr it then follows that k is the same function of T that μ is. Thus, corresponding to each of the six μ functions there is a relation

$$k = k_1\varphi \quad [17]$$

where φ is φ_C, φ_B, φ_K, φ_{S175}, φ_{S273}, or φ_{S375} as required, and k_1 is the value of k in the undisturbed stream.

Figs. 2, 3, and 4 show the distribution of θ, $\varphi\theta'$, U, $\varphi U'$, V for $\Pr = 0.733$ and $b = 1.6$, according to the various φ's. The noteworthy fact is that all the curves in a given group, except the φ_C and φ_B curves, fall very near to one another. The use of φ_K has certain practical advantages over the Sutherland formula, e.g.,

[4] Used by Busemann (3), who gave a few special solutions of the present problem for $\Pr = 1$.

[5] von Kármán and Tsien (2) have given for $\Pr = 1$ a much more comprehensive set of solutions than Buscmann's.

[6] The Sutherland constant 114 in Sutherland's formula is for air in the range 0–300 C. It has been used here for the case $T_1 = 175$ C as well as for $T_1 = 273$ C and $T_1 = 375$ C.

it is independent of the value of T_1 and contains no constant corresponding to the Sutherland constant. In consequence of these practical advantages and the results shown in the curves, $\varphi_K = \theta^{0.768}$ has been chosen as the temperature function $\mu/\mu_1 (= k/k_1)$ to be used in the sequel. The exponent 0.768 fits the experimental data for air quite well. All the data in or near the range 0–100 C reviewed by Chapman and Cowling (4) give an average value of 0.84 with an extreme variation of ±0.20. The viscosity of steam requires exponents from 1.1 to 0.25 for different pressures from 0 to 1500 psi. The exponent 0.768 corresponds to a pressure of about 200 psi. Table 1 summarizes in numerical form certain of the results.

TABLE 1

Pr = 0.733 and b = 1.6

Viscosity ratio μ/μ_1	θ_0	φ_0	U_0'	$CD(\mathrm{Re})^{1/2} = 4\varphi_0 U_0'$	V (At main stream)
φ_C	1.67	1.000	0.274	1.096	1.37
φ_B	1.66	1.290	0.234	1.208	1.53
φ_K	1.66	1.480	0.215	1.273	1.645
φ_{S175}	1.66	1.538	0.211	1.300	1.66
φ_{S273}	1.66	1.468	0.217	1.274	1.63
φ_{S375}	1.655	1.430	0.221	1.264	1.60

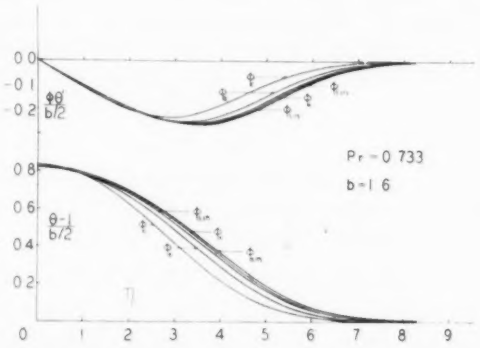

FIG. 2 VARIATION OF θ AND $\varphi\theta'$ FOR VARIOUS φ'S WHEN PR = 0.733 AND b = 1.6

(Curves for φ_{S273} are in each case very close to, and give smaller absolute values than, the φ_K curves.)

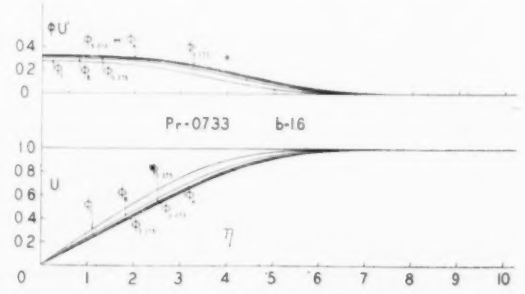

FIG. 3 VARIATION OF U AND $\varphi U'$ FOR VARIOUS φ'S WHEN PR = 0.733 AND b = 1.6

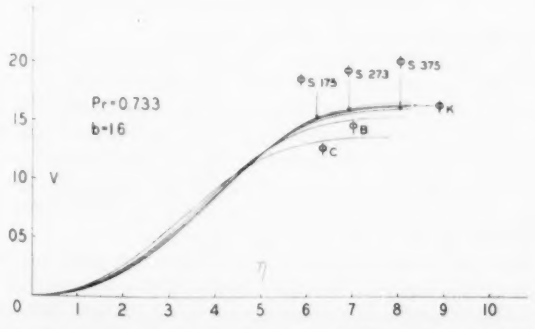

FIG. 4 VARIATION OF V FOR VARIOUS φ'S WHEN PR = 0.733 AND b = 1.6

II—DISTRIBUTIONS FOR $\mu/\mu_1 = \varphi_K$

In this part (II) all results are for $\mu/\mu_1 = \varphi_K$. Figs. 5*a* and 5*b*

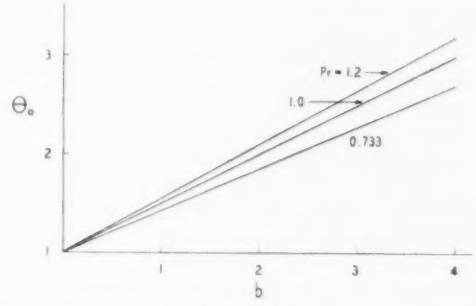

FIG. 5*a* VARIATION OF θ_0 WITH b FOR VARIOUS VALUES OF PR

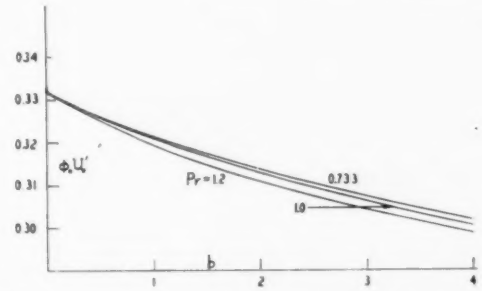

FIG. 5*b* VARIATION OF $\varphi_0 U_0'$ WITH b FOR VARIOUS VALUES OF PR ($\varphi_0 = \varphi_K$ AT PLATE WALL, $\eta = 0$.)

show conditions at the plate wall for various Pr's and b in the range $0 \leq b \leq 4$. It is noteworthy that $\varphi_0 U_0'$ varies little, and θ_0 is very closely a linear function of b. Since $\varphi_0 U_0'$ has such small variation, it is possible to write

$$C_D(\mathrm{Re})^{1/2} = 1.26 \quad \ldots\ldots [18]$$

as an approximation holding to within 5 per cent for all the points represented. For $b < 2$

$$C_D(\mathrm{Re})^{1/2} = 1.28 \quad \ldots\ldots [19]$$

is a better approximation, good to within 3 per cent. Table 2 gives data for the plate wall and, in the case of V, at the "boundary" between boundary layer and the main stream. The values of $C_D\,(\mathrm{Re})^{1/2}$ for Pr = 1.00 check those of other investigators (2) to well within 1 per cent.

Figs. 6, 7, and 8 show the distributions for Pr = 0.733, with b as the parameter. A comparison with similar curves for $\mu/\mu_1 = \varphi_C$ shows that the spread of the curves is appreciably greater,

TABLE 2

Pr = All values	0	1.000	1.000	1.327
Pr = 0.733	0.1	1.042	1.032	1.319
	0.4	1.170	1.128	1.308
	0.9	1.380	1.280	1.289
	1.6	1.675	1.486	1.269
	4.0	2.705	2.147	1.209
Pr = 1.00	0.1	1.050	1.038	1.318
	0.4	1.198	1.149	1.308
	0.9	1.445	1.327	1.288
	1.6	1.793	1.566	1.264
	4.0	2.991	2.320	1.204
Pr = 1.20	0.1	1.053	1.041	1.320
	0.4	1.215	1.161	1.305
	0.9	1.484	1.354	1.284
	1.6	1.876	1.621	1.256
	4.0	3.186	2.435	1.196

indicating that the variation of μ markedly accentuates the dependence of the distributions on b. This is particularly interesting in the case of θ, since the value θ_0 of θ at the plate wall is, for all cases shown, within 1 per cent of the value for μ constant. It may also be noted that the thicknesses of the boundary layer δ_v for velocity and of the boundary layer δ_T for temperature have changed from the φ_C case.

Fig. 8 shows how V builds up from the plate wall to the main stream. It is important to distinguish here the "main stream" and the "undisturbed stream." Until the velocity component v corresponding to V at the beginning of the main stream has been returned to zero, the undisturbed stream is not reached. Thus adjacent to the boundary layer is another region in which the v readjustment takes place. However, since $v = (\nu_1 u_1/x)^{1/2} V$, the greater x the less v, other things being equal, and at any large distance from the edge of the plate ($x = 0$) the velocity component v is practically zero.

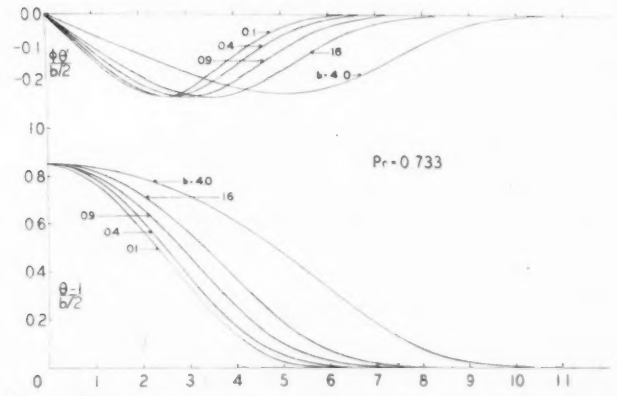

FIG. 6 VARIATION, FOR PR = 0.733, OF θ AND $\varphi\theta'$ IN BOUNDARY LAYER

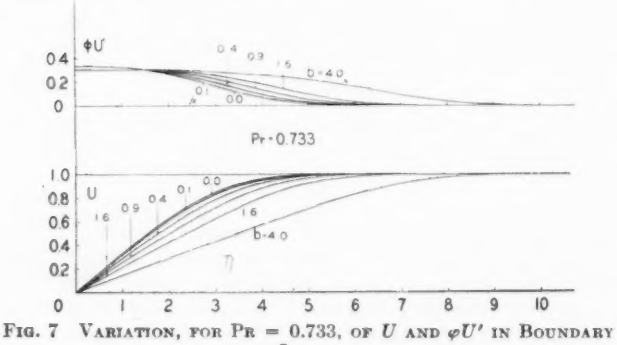

FIG. 7 VARIATION, FOR PR = 0.733, OF U AND $\varphi U'$ IN BOUNDARY LAYER

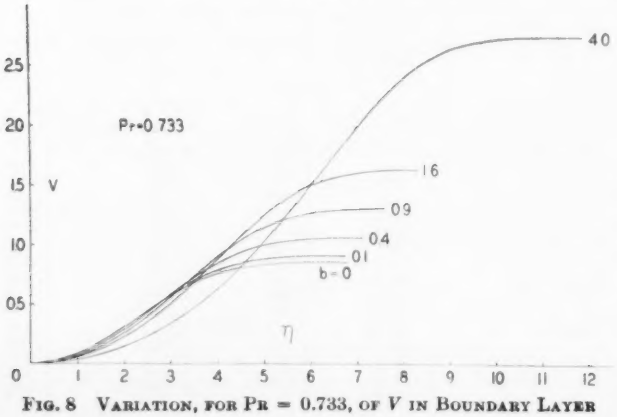

FIG. 8 VARIATION, FOR PR = 0.733, OF V IN BOUNDARY LAYER

The time rate of transfer of thermal energy across unit area perpendicular to the Y direction is

$$-k\frac{\partial T}{\partial y} = -\left[k_1 T_1 \left(\frac{u_1}{\nu_1 x}\right)^{1/2}\right]\varphi\theta' \quad [20]$$

and thus is proportional to $\varphi\theta'$ as given in Fig. 6. Likewise the shear stress τ through the boundary layer is given by

$$\tau = \mu\frac{\partial u}{\partial y} = \left[\mu_1 u_1 \left(\frac{u_1}{\nu_1 x}\right)^{1/2}\right]\varphi U' \quad [21]$$

and consequently is proportional to $\varphi U'$ as given in Fig. 7. It is for these reasons that $\varphi\theta'$ and $\varphi U'$ have been plotted rather than θ' and U'.

III—THE EFFICIENCIES AND FLOW COEFFICIENTS OF A PASSAGE

In the previous parts of this paper the variations of the temperature and velocity components through the boundary layer have been considered. These, together with the fact that the pressure is taken constant throughout the whole flow field, completely determine all other properties. For example the density ρ is calculated from

$$\rho/\rho_1 = 1/\theta \quad [22]$$

If the flow along a wall were to be measured, impact and static pressure measurements would be made and the corresponding fluid velocity would be calculated from the formula

$$u^2 = 2(h_a - h) = 2c_p T_a\left[1 - (p/p_a)^{(\gamma-1)/\gamma}\right] \quad [23]$$

Here u^2 is written instead of $u^2 + v^2$ since $v = V(\nu_1 u_1/x)^{1/2}$ and is therefore very small. The temperature T_a is the temperature reached by the fluid at any point in the stream when its velocity is destroyed isentropically. In engineering practice it is customary to assume that T_a is equal to the isentropic stagnation temperature of the undisturbed stream, T_{a1}. In general, however

$$\frac{T_a}{T_{a1}} = \frac{T + (u^2/2c_p)}{T_1 + (u_1^2/2c_p)} = \frac{\theta + (U^2 b/2)}{1 + b/2} \quad [24]$$

and thus T_a/T_{a1} varies from $\dfrac{\theta_0}{1 + b/2}$ at the wall to 1 outside the boundary layer. At the wall therefore T_a/T_{a1} is less than, equal to, or greater than 1 according as Pr is less than, equal to, or greater than 1. The temperature T_a is constant and equal to T_{a1} throughout the boundary layer for a fluid with Pr = 1, as can be seen from Equation [11]. If Pr $\neq$ 1, T_a varies from its value at the wall, passes through 1 somewhere in the boundary layer, and then approaches 1 from the opposite side. This variation is required by the fact that the enthalpy plus kinetic energy of the whole stream must remain constant in steady flow in the absence of external heat or work transfers.

Fig. 9 shows the variation through the boundary layer of the isentropic stagnation temperature T_a, the actual fluid temperature T, and the impact pressure p_a for the special case Pr = 0.733, b = 0.4, i.e., air flowing at the speed of sound. The variations of properties through the boundary layer in this special case are further pictured on a dimensionless Mollier chart, Fig. 10. The lines representing flow per unit area are modified through the boundary layer because of the heat transfers.

Since the isentropic stagnation temperature does not remain constant throughout the boundary layer, it is natural to inquire what error is made in efficiency and flow calculations by assuming it so. Consider the special case of a two-dimensional nozzle with a parallel throat 4 in. long and 1¼ in. wide, see Fig. 11. As-

sume that air flows at the speed of sound through this nozzle. The efficiency of such a passage is defined as the kinetic energy carried out of the nozzle per unit time divided by that which would have been carried out by the same fluid had the flow been isentropic. The efficiency for this case with a boundary layer at each wall is

$$\epsilon = \frac{\int (\rho/2)u^3 dA}{(u_1^3/2)\int \rho u dA} = \frac{\int^\eta (U^3/\theta)d\eta}{\int_0^\eta (U/\theta)d\eta} \quad \ldots\ldots [25]$$

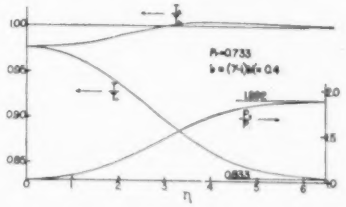

FIG. 9 VARIATION, FOR PR = 0.733 AND b = 0.4, OF T, T_a, AND p_a IN BOUNDARY LAYER

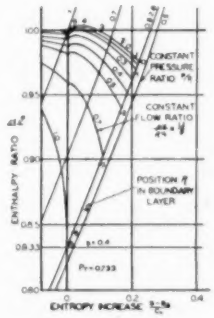

FIG. 10 VARIATION, FOR PR = 0.733 AND b = 0.4, OF FLUID PROPERTIES IN BOUNDARY LAYER

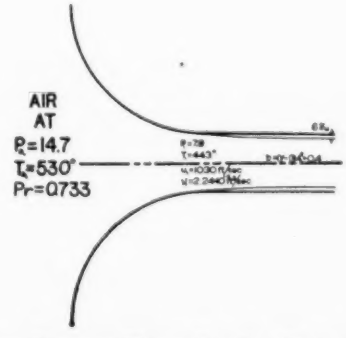

FIG. 11 NOZZLE THROUGH WHICH CRITICAL FLOW OF AIR OCCURS UNDER CONDITIONS SHOWN

in which A, the cross-sectional area, is assumed directly proportional to η. The integration must be carried out numerically through the boundary layer, to $\eta = 6$ for the case under consideration. Beyond $\eta = 6$, $U = 1$ and $\theta = 1$ so that the efficiency becomes

$$\epsilon = \frac{\int_0^6 (U^3/\theta)d\eta + \eta - 6}{\int_0^6 (U/\theta)d\eta + \eta - 6} \quad \ldots\ldots [25a]$$

For convenience in the interpretation of traverse tests of nozzles, the efficiency is commonly defined as the area mean kinetic energy per unit mass divided by the corresponding quantity for frictionless flow. The kinetic energy is determined at each point by measurements of impact and static pressure and the use of Equation [23] with T_{a1} used for T_a.

$$\epsilon_1 = \frac{\int c_p T_{a1}[1 - (p/p_a)^{(\gamma-1)/\gamma}]\, dA}{u_1^2 A/2} = \frac{\int_0^\eta U^2(T_{a1}/T_a)d\eta}{\eta} \quad [26]$$

$$= \frac{\int_0^6 U^2(T_{a1}/T_a)d\eta + \eta - 6}{\eta}$$

These efficiencies differ for two reasons:

1 The flow per unit area in the boundary layer has been reduced by the friction. The over-all efficiency of a machine containing a nozzle indicates how well the machine uses the fluid which actually flows through it. The static test efficiency should do the same. Thus a flow mean kinetic energy should be used instead of an area mean.

2 The isentropic stagnation temperature T_a was assumed equal to the isentropic stagnation temperature T_{a1} of the undisturbed stream.

To separate these two effects another efficiency is defined making the first assumption but not the second

$$\epsilon_2 = \frac{\int (u^3/2)dA}{u_1^2 A/2} = \frac{\int c_p T_a[1 - (p/p_a)^{(\gamma-1)/\gamma}]\, dA}{u_1^2 A/2} = \frac{\int_0^\eta U^3 d\eta}{\eta}$$

$$= \frac{\int_0^6 U^3 d\eta + \eta - 6}{\eta} \quad \ldots [27]$$

For the special case of Fig. 11, the boundary-layer thickness at the end of the passage, assuming zero thickness at the beginning of the passage, is

$$\delta_u = (\nu_1 L/u_1)^{1/2} = 0.0102 \text{ in.}$$

Half the width of the passage expressed in terms of η is therefore

$$\eta = y/\delta_u = 0.875/0.0102 = 85.8$$

TABLE 3

ϵ	$= \frac{\text{Actual kinetic energy}}{\text{Kinetic energy of same fluid if frictionless flow}}$	= 98.3 per cent
ϵ_1	$= \frac{\text{Area mean kinetic energy per unit mass } (T_a = T_{a1})}{\text{Kinetic energy per unit mass if frictionless flow}}$	= 97.3 per cent
ϵ_2	$= \frac{\text{Area mean kinetic energy per unit mass } [T_a = T_a(\eta)]}{\text{Kinetic energy per unit mass if frictionless flow}}$	= 97.0 per cent
C_d	$= \frac{\text{Actual flow}}{\text{Flow if frictionless}}$	= 97.8 per cent
C_u	$= \frac{\text{Area mean velocity assuming } T_a = T_{a1}}{\text{Velocity if frictionless flow}}$	= 98.3 per cent

of which $\eta = 6$ is boundary layer. Thus about 7 per cent of the area of the stream is affected by the boundary layer.

When the integrals in the efficiency expressions are evaluated, there results the comparison as shown in Table 3.

The actual efficiency of energy transformation is about one per cent better than that indicated by a traverse of the passage for the special case here studied. The major portion of the error arises in neglecting the reduction in flow per unit area in the boundary layer.

The flow coefficient of a passage is defined as the actual flow through the passage divided by the flow that would pass through the passage if it were frictionless and the pressure drop remained the same. In terms of the present notation

$$C_d = \frac{\int \rho u dA}{\rho_1 u_1 A} = \frac{1}{\eta}\int_0^\eta (U/\theta)d\eta = \frac{\int_0^6 (U/\theta)d\eta + \eta - 6}{\eta} \quad [28]$$

If the velocity were calculated from the measured pressures and

the assumption that $T_s = T_{s1}$, the velocity coefficient would be calculated from

$$C_s = \frac{\int 2c_p T_{s1}[1 - (p/p_s)^{(\gamma-1)/\gamma}]^{1/2}\, dA}{u_1 A} = \frac{1}{\eta}\int^{\eta} U \frac{T_{s1}}{T_s}\, d\eta = \frac{\int_0^6 U(T_{s1}/T_s)d\eta + \eta - 6}{\eta} \quad [29]$$

The velocity coefficients and the flow coefficients are the same for incompressible fluids and are sometimes erroneously assumed so for compressible fluids. The flow coefficient and velocity coefficient are shown in Table 3.

It is often supposed that the velocity coefficient squared is equal to the efficiency of the nozzle. The magnitude of the error made by assuming that the mean velocity squared is the square of the mean velocity is evident by the comparison

$$\epsilon_1 = 97.3 \text{ per cent}, \quad C_s^2 = 96.6 \text{ per cent}$$

For accuracy of ±1 per cent or better, a careful distinction should be made between the various definable energy, flow, and velocity coefficients.

The foregoing calculations are poor approximations to the coefficients for nozzles but do serve the purpose of showing the differences between the various definitions.

Buckling of the Circular Plate Beyond the Critical Thrust

By K. O. FRIEDRICHS[1] and J. J. STOKER,[2] NEW YORK, N. Y.

In this paper a complete mathematical solution of the problem of the buckling with large deflections of a thin circular plate under uniform radial pressure is given, assuming radial symmetry. Buckling takes place as soon as the prescribed thrust p_e at the edge reaches a certain critical value p_E. Thin plates do not, however, fail if the thrust p_e is increased beyond p_E. It is of importance, then, to determine the stresses when the ratio $\Lambda = p_e/p_E$ becomes greater than unity. This problem, which is a nonlinear one, is solved by two methods for finite values of Λ; also an asymptotic solution is given for the limit state when Λ tends to infinity. The most notable single result is that the membrane stresses for large values of Λ become tensions in the interior of the plate and change abruptly to compressions in a narrow "boundary layer" at the edge of the plate. Curves showing the behavior of the deflection and the stresses are given for a series of values of Λ. Such curves show clearly, in particular, that the limit state is approached quite closely for relatively small values of Λ, i.e., $\Lambda > 5$. In closing, the authors discuss the relation between their results and von Kármán's theory of effective width for the buckling of rectangular plates.

Notation

x, y = rectangular coordinates
r = distance from center
R = radius of plate
h = thickness of plate
E = Young's modulus
ν = Poisson's ratio
$\gamma = [12(1 - \nu^2)]^{-1/2}$
$\eta = \gamma h/R$ slenderness ratio
w = deflection of the middle surface
$q = -Rr^{-1}dw/dr$
q_e = slope of the middle surface at the edge
φ = Airy's stress function
$-p$ = radial membrane stress
$-p_c$ = circumferential membrane stress
σ_b = radial bending stress at the upper surface
σ_{cb} = circumferential bending stress at the upper surface
τ_b = shearing stress due to bending at the upper surface
p_0, p_{c0}, σ_{b0} = values of stresses at the center of the plate
p_e, p_{ce}, σ_{be} = values of stresses at the edge of the plate
p_E = critical value of p_e
$\Lambda = p_e/p_E$

If a straight slender column is subjected to gradually increasing thrusts applied at its ends, it will become instable and buckle when a certain critical value of the thrust is reached. If the thrust is increased a small amount beyond the critical value, the column will generally collapse completely. The behavior of a thin flat plate subjected to compressive forces at its edges and in its plane is quite different. The plate will become instable when the compressive forces reach certain critical values, but the forces can be increased considerably above such values without causing a collapse of the plate. The fundamental reason for this experimentally well-established difference in the behavior of column and plate is that a straight line (the axis of the column) can be bent into a curve without changing its length, while a plane surface, the edge of which is restrained, cannot be deformed without stretching the surface. Thus, when the plate buckles, the stretch which results relieves the central part of the plate of a portion of the compressive stresses and as a consequence the plate is relatively much stiffer than the column.

It is a matter of practical importance to determine the strength of thin plates when subjected to loads greater than those at which buckling begins, because such thin-walled structures are used extensively, for example, in aircraft, where lightness combined with maximum strength is desired and where buckling is permissible as long as it does not result in failure.

A formula for the design of rectangular plates for thrusts beyond the lowest buckling thrust has been developed by von Kármán. It is based on the assumption that the compressive stresses tend to become concentrated in a strip near the edge of the plate. Such an edge effect has been observed, in fact, by a number of experimenters (2, 3, 9, 12, 13, 18, 19).[3]

The purpose of this investigation is to give a complete mathematical solution for the case of the circular plate with simply supported edges, buckled with radial symmetry under the action of a uniformly distributed edge thrust. The results include, in particular, an explanation and discussion of an edge effect which is found here as a natural part of the solution. Important and interesting conclusions can be drawn which retain at least qualitative significance for the case of the rectangular plate—the case of more immediate practical importance.

The mathematical formulation of the problem of the buckled plate involves a pair of nonlinear differential equations derived by von Kármán for the bending of thin plates with large deflections (8). Various writers (6, 10, 11, 12, 13, 14, 16, 20, 24) have solved these equations using the perturbation and energy methods in order to obtain solutions valid at least for a limited range of the ratio Λ of applied pressure p_e to the lowest buckling pressure p_E. Such solutions deal in the main with the rectangular plate. An exact solution for the rectangular plate valid for an unlimited range of the ratio Λ presents seemingly insurmountable difficulties; for the circular plate,[4] however, the authors obtain

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until April 10, 1942, for publication at a later date. Discussion received after the closing date will be returned.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors and not those of the Society.

[3] Numbers in parentheses refer to the Bibliography.

[4] The problem of the bending of a circular plate under lateral pressure and edge moment has been solved by Way (22) by an exact method for a rather large range of applied load.

Federhofer (24) has solved the problem of the buckling of the circular plate for simply supported and clamped edges. In the former case, which is the same as that treated here, the method of Federhofer yields accurate results up to about $\Lambda = 1.25$.

rigorous solutions valid for an unlimited range of Λ. The existence of an edge effect can then be derived by an asymptotic treatment for $\Lambda \to \infty$, which presents some mathematical analogy with the Prandtl boundary-layer theory for the flow of a viscous fluid around an obstacle (15). It is possible, as will be shown, to design plates for arbitrarily large values of Λ without exceeding given limits for the maximum stresses and without violating the assumptions upon which the von Kármán equations rest.

In the present paper are given the results of an investigation together with an outline of the mathematical methods. A detailed explanation, with proofs, of the mathematical methods will be given in a forthcoming paper (26).[5]

1—Mathematical Formulation

Consider a plane circular plate with radius R and thickness h subjected to a constant radial thrust at the edge; assume the plate simply supported, i.e., that deflection and radial bending moment vanish at the edge. Further, assume that the deflection w of the middle surface depends only upon the distance r from the center of the plate; a consequence of this assumption is that the radial and circumferential stresses also depend only upon r. Quantities which carry the subscript e or 0 refer to their values at the edge ($r = R$) or center ($r = 0$) respectively.

The von Kármán equations in Cartesian coordinates x and y are

$$E^{-1}\nabla^4\varphi = \left(\frac{\partial^2 w}{\partial x\,\partial y}\right)^2 - \frac{\partial^2 w}{\partial x^2}\frac{\partial^2 w}{\partial y^2} \quad \ldots\ldots [1]$$

$$\gamma^2 h^2 E \nabla^4 w = \frac{\partial^2\varphi}{\partial y^2}\frac{\partial^2 w}{\partial x^2} - 2\frac{\partial^2\varphi}{\partial x\,\partial y}\frac{\partial^2 w}{\partial x\,\partial y} + \frac{\partial^2\varphi}{\partial x^2}\frac{\partial^2 w}{\partial y^2} \quad \ldots\ldots [2]$$

where φ is the Airy stress function, E the modulus of elasticity, and $\gamma = [12(1 - \nu^2)]^{-1/2}$, where ν is Poisson's ratio. These equations imply that the stresses in the plate are given by combination of two stress systems, the bending stresses and the "membrane" stresses.

For the case of the circular plate with radial symmetry these nonlinear equations can be greatly simplified. Since φ and w depend only on r, the operation ∇^2 reduces to

$$\nabla^2 = \frac{d^2}{dr^2} + r^{-1}\frac{d}{dr} = r^{-1}\frac{d}{dr}\,r\,\frac{d}{dr} \quad \ldots\ldots [3][6]$$

and the von Kármán equations assume the form

$$E^{-1}r^{-1}\frac{d}{dr}\,r\,\frac{d}{dr}\,r^{-1}\frac{d}{dr}\,r\,\frac{dw}{dr} = -\frac{d^2 w}{dr^2}\,r^{-1}\frac{dw}{dr} \quad \ldots\ldots [4]$$

$$\gamma^2 h^2 E r^{-1}\frac{d}{dr}\,r\,\frac{d}{dr}\,r^{-1}\frac{d}{dr}\,r\,\frac{d\varphi}{dr} = \frac{d^2\varphi}{dr^2}\,r^{-1}\frac{dw}{dr} + r^{-1}\frac{d\varphi}{dr}\frac{d^2 w}{dr^2} \quad \ldots [5]$$

The right members here can be written in the form

$$-\frac{1}{2}\,r^{-1}\frac{d}{dr}\left(\frac{dw}{dr}\right)^2 \quad \text{and} \quad r^{-1}\frac{d}{dr}\left(\frac{d\varphi}{dr}\frac{dw}{dr}\right);$$

hence the equations can be integrated

$$E^{-1}r\frac{d}{dr}\,r^{-1}\frac{d}{dr}\,r\,\frac{dw}{dr} = -\frac{1}{2}\left(\frac{dw}{dr}\right)^2 + \text{const} \quad \ldots\ldots [6]$$

$$h^2 E r\frac{d}{dr}\,r^{-1}\frac{d}{dr}\,r\,\frac{d\varphi}{dr} = \frac{d\varphi}{dr}\frac{dw}{dr} + \text{const} \quad \ldots\ldots [7]$$

Since the left members and also dw/dr vanish for $r = 0$, the constants are zero. The equations are further simplified by introducing the quantities

$$p = -r^{-1}\,d\varphi/dr, \quad q = -Rr^{-1}\,dw/dr$$

the operation

$$\Gamma = R^{-2}r^{-1}\frac{d}{dr}\,r^{-1}\frac{d}{dr}\,r^{-2} = R^{-2}r^{-3}\frac{d}{dr}\,r^3\frac{d}{dr}$$

and the constant

$$\eta = \gamma h/R$$

which may be called the "slenderness ratio." Then the equations assume the form

$$E^{-1}\Gamma p = q^2/2 \quad \ldots\ldots [8]$$

$$E\Gamma q + pq = 0 \quad \ldots\ldots [9]$$

The quantity $-p$ is the radial membrane stress; the authors prefer to denote a membrane stress by $-p$ rather than by σ since it is a compression when buckling begins, i.e., p is then positive. The significance of the quantity q is that $(r/R)q$ is the slope of the deflected plate; in particular, q_e, the value of q at the edge, is the slope at the edge; the quantity $-q/R = r^{-1}dw/dr$ could also be interpreted as the circumferential curvature of the deflected plate.

The boundary conditions to be satisfied at the edge ($r = R$) in terms of p and q are

$$rdq/dr + (1 + \nu)q = 0 \quad \ldots\ldots [10]$$

and

$$p = p_e \quad \ldots\ldots [11]$$

The important quantity p_e is the prescribed radial compression at the edge. Equation [10] states that the bending moment at the edge vanishes. The conditions for $r = 0$ are

$$dp/dr = 0, \quad dq/dr = 0 \quad \ldots\ldots [12, 13]$$

which, on account of symmetry, imply regularity of p and q at the center of the plate.

Of the constants R, h, E, ν, p_e, which characterize the problem, only two, ν and $p_e/E\eta^2$, are essential in the sense that deflection and stresses in two plates having the same values of these ratios differ only by constant multipliers. This can be seen by introducing r/R, $p/E\eta^2$, q/η as new variables; the formulation of the problem obtained in this way contains only ν and $p_e/\eta^2 E$ as parameters.

Once p and q have been determined, the circumferential membrane stress $-p_c$ and the radial bending stress σ_b at the upper surface of the plate are given by

$$p_c = rdp/dr + p \quad \ldots\ldots [14]$$

and

$$\sigma_b = 6\gamma\eta[(rdq/dr) + (1 + \nu)q] \quad \ldots\ldots [15]$$

The deflection w is given by

$$w = R^{-1}\int^R qr^{-1}dr \quad \ldots\ldots [16]$$

thus $w(R) = 0$.

For sufficiently small values of $p_e/\eta^2 E$ there will be no buckling of the plate—corresponding to the fact that the mathematical problem has then as sole solution $q \equiv 0$, $p \equiv$ const. At a certain value p_E of p_e buckling will begin; for $p_e > p_E$ there will

[5] For a preliminary report, see reference (5).

[6] Cf., e.g., reference (21).

be two stable buckled states[7] differing only in the sign of w, while the state $w \equiv 0$, which continues to be a possible state of equilibrium, is instable. The critical value p_E of p_e is given by $p_E/\eta^2 E = 4.24$ when the value 0.318 is taken[8] for Poisson's ratio ν. This value of the critical or "Euler" pressure p_E is obtained from Equation [9] by assuming p to be constant, that is, by the standard linear treatment of the buckling problem. Cf. reference (26).

Instead of using $p_e/\eta^2 E$ as essential parameter, the authors prefer to use the ratio $\Lambda = p_e/p_E = p_e/4.24\eta^2 E$ in what follows.

2—Methods of Solution

There are at least two methods available for solving this problem: the perturbation and the power-series methods. Both methods are presented. The perturbation method is found to be manageable only for a rather low range of values of the ratio Λ. This fact is in itself of interest since the perturbation method has been used extensively in the case of the rectangular plate, where an analogue of the power-series method is not available. The power-series method can be used successfully for a much higher range of values of Λ if solutions for a low range of values of Λ have been obtained by some other means, for example by the perturbation method. In general, the authors recommend the power-series method for problems similar to the present one, and for this reason it will be explained in some detail. However, the power-series method also becomes cumbersome as Λ increases, and eventually one is forced to turn to an asymptotic treatment.

3—Perturbation Method

This method consists in a development of p and q with respect to a parameter ϵ, which may be chosen, for example, as $\epsilon = \sqrt{(\Lambda - 1)}$:

$$p = p^{(0)} + \epsilon^2 p^{(2)} + \epsilon^4 p^{(4)} + \ldots\ldots\ldots\ldots [17]$$

$$q = \epsilon q^{(1)} + \epsilon^3 q^{(3)} + \ldots\ldots\ldots\ldots\ldots [18]$$

Upon substituting in the original differential equations and equating coefficients of like powers of ϵ, one obtains a sequence of linear differential equations for $p^{(0)}$, $q^{(1)}$, $p^{(2)}$, $q^{(3)}$, ..., which can be solved successively, though with great labor. The quantity $p^{(0)}$ proves to be a constant identical with the lowest value p_E of p_e for which buckling begins and is the same as that obtained by the linear theory (26); its value, as stated previously, is $p^{(0)} = p_E = 4.24\eta^2 E$.

The authors have computed $q^{(1)}$ to $q^{(5)}$ and $p^{(0)}$ to $p^{(6)}$. The convergence is satisfactory only for a small range of values of $\Lambda = p_e/p_E$, namely, for q up to $\Lambda = 1.2, 1.8, 2.5$ if terms of the first, third, and fifth orders respectively are included; and for p up to $\Lambda = 1.4, 2.2, 2.8$ for terms of the second, fourth, and sixth orders respectively. For the other stresses the convergence is not quite as good. Nevertheless, even for these low values of Λ, some distinctive and rather surprising qualitative phenomena of the buckling are found. See section 5.

In Fig. 1 curves are shown which indicate the accuracy of the successive approximations. For this purpose it was chosen to plot $\sigma_b/p_e\sqrt{\Lambda}$ as a function of r/R for $\Lambda = 2.5$. This appears to be the least accurately obtained stress. The figure shows the curves obtained by taking successively terms up to first, third, and fifth orders in ϵ, together with the curve obtained by an exact solution to be discussed in the next section. The curve obtained by taking terms up to fifth order would give for the stress σ_b values in error by as much as 10 per cent.[9]

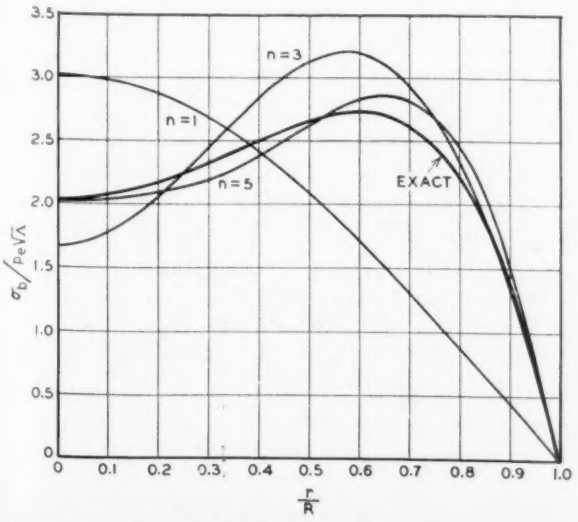

Fig. 1 Convergence of Perturbation Method for $\Lambda = 2.5$

4—Power-Series Method

The power-series method was used by Way (22) for solving the von Kármán equations as applied to the bending of circular plates under lateral loads and edge moment. See also reference (7). The method consists in setting up series for p and q in powers of r, with assumed values for the first coefficient of each series, i.e., for the values of p and q at the center of the plate.

Here are introduced a new independent variable

$$\alpha = AR^{-1}r, \quad 0 \leq \alpha \leq A \ldots\ldots\ldots\ldots [19]$$

and the new functions to replace p and q

$$\pi = A^{-2}p/\eta^2 E, \quad \kappa = A^{-2}q/\eta \ldots\ldots\ldots\ldots [20]$$

Differential Equations [8] and [9] assume the form

$$\alpha^{-3}\frac{d}{d\alpha}\left(\alpha^3\frac{d\pi}{d\alpha}\right) = \frac{1}{2}\kappa^2 \ldots\ldots\ldots\ldots [21]$$

$$\alpha^{-3}\frac{d}{d\alpha}\left(\alpha^3\frac{d\kappa}{d\alpha}\right) + \pi\kappa = 0 \ldots\ldots\ldots\ldots [22]$$

with boundary conditions

$$\frac{d\pi}{d\alpha} = 0, \quad \frac{d\kappa}{d\alpha} = 0 \quad \text{for} \quad \alpha = 0 \ldots\ldots\ldots [23]$$

$$B(\alpha) \equiv \alpha\frac{d\kappa}{d\alpha} + (1+\nu)\kappa = 0 \quad \text{for} \quad \alpha = A \ldots [24]$$

$$\pi = \pi_e \quad \text{for} \quad \alpha = A \ldots\ldots\ldots\ldots [25]$$

Instead of prescribing π_e and A, which would be equivalent to the

[7] That the equations have only two solutions is a consequence of their nonlinearity; linear theories of buckling always yield infinitely many buckled states differing only by constant factors.

[8] This value for ν, a typical value for aluminum alloy, was taken to facilitate calculation of p_E and was also used throughout the calculations.

[9] Marguerre (13) mentions that his solutions for the rectangular plate, which implied two perturbations, may perhaps be valid up to $\Lambda = 20$; Timoshenko (20) applies his Ritz method with three constants for $\Lambda = 59.7$ and mentions that an additional constant would be necessary only for $\Lambda > 50$. In the simpler case of the circular plate it is found that values of Λ of these magnitudes cannot be treated with three perturbations. In fact such values of Λ lead to solutions already well in the asymptotic range. See section 6.

The method of Federhofer (24), see also footnote,[4] corresponds to the determination of $q^{(1)}$ and $p^{(2)}$ by the Galerkin method. Federhofer's numerical results coincide with the authors' quite well up to $\Lambda = 1.2$; they deviate from them by 10 per cent for $\Lambda = 1.5$.

original formulation, one proceeds as follows: $\pi(0)$ and $\kappa(0)$ are chosen, A is determined by solving Equation [24], and π_e is calculated from Equation [25]; p and q are then determined from Equation [20].

It is easily seen that power series for π and κ contain only even powers of α

$$\pi = \sum_{k=0}^{\infty} \pi_k \alpha^{2k}, \quad \kappa = \sum_{k=0}^{\infty} \kappa_k \alpha^{2k} \ldots\ldots [26]$$

Upon insertion of these power series into Equations [21] and [22] one obtains the following recursion formulas for π_k and κ_k

$$\left.\begin{aligned} 2k(2k+2)\pi_k &= \frac{1}{2}\sum_{n+m=k-1} \kappa_m \kappa_n \\ 2k(2k+2)\kappa_k &= -\sum_{m+n=k-1} \pi_m \kappa_n \end{aligned}\right\} \ldots\ldots [27]$$

After having chosen $\pi(0) = \pi_0$ and $\kappa(0) = \kappa_0$ the successive coefficients are calculated from these formulas. Equation [24] becomes

$$B(\alpha) \equiv \sum_{k=0}^{\infty} (2k + 1 + \nu)\kappa_k \alpha^{2k} = 0 \ldots\ldots [28]$$

It must be solved for its lowest root $\alpha = A$.

One of the principal difficulties encountered in working with the power-series method consists in solving Equation [28]. Unless $A \sim 1$, the amount of labor involved in its solution is excessive. One reason for this is that otherwise one has no means of knowing the accuracy with which π_k and κ_k need be calculated and also the number of such coefficients necessary for reasonable accuracy. It might also be noted that the left side of Equation [28] changes rapidly with changes in α, and hence it is difficult to find the root A if no advance estimate of its value is available. What is evidently required for this purpose is a good estimate for π_0 and κ_0. This is, of course, also necessary if the solution is desired for a given value of Λ. One of the main purposes of this paper is to give solutions over a considerable range of values of Λ and with a fairly even distribution of such values.[10] For this objective it was found that solutions by the perturbation method were very helpful as a starting point.

As an example, the calculations are presented which yielded the solution for $\Lambda = 14.7$ (the highest value of Λ for which the power-series method was used). What was desired was the solution for $\Lambda = 15$; by extrapolation from previously calculated solutions,[11] which included values of Λ up to 7.3, it was found that $\kappa_0 = 7.0$ and $\pi_0 = -44.0$ were reasonable values for the first coefficients in the series. Equations [27] then lead to the coefficients π_k and κ_k given in Table 1.

TABLE 1

15	2.65	3.60			

In order to solve Equation [28] $B(1)$ was calculated and found to be −155.0 instead of zero. To apply Newton's method $\alpha dB/d\alpha$ was calculated for $\alpha = 1$ and found to be −7800. The resulting new value for A, replacing the value 1, is then $A = 0.98$. Whence $B(0.98) = -9.14$. Repeating this process once more, $A = 0.978$, $B(A) = +2.16$. The value 2.16 for $B(A)$ is of the same order as the values of the last terms in the series for $B(\alpha)$; therefore further improvement in the value of A is not possible using these coefficients. With this value of A, the quantity π_e was calculated from Equation [25] and value of $\Lambda = \pi_e A^2 \eta^2 E/p_E$ was found to be 14.7 instead of 15.

The number of coefficients necessary for sufficient accuracy increases with Λ. For $\Lambda = 14.7$, as we have seen, 30 terms are needed; 23 terms suffice for $\Lambda = 7.3$.

The authors recommend a similar procedure for problems of this type involving circular plates with radial symmetry.

5—Discussion of Results

Curves are given showing the behavior of the deflection w, the slope $-dw/dr = rq/R$, the radial membrane stress p, the circumferential membrane stress p_c, and the radial bending stress σ_b. Actually, these quantities are multiplied by appropriate factors, so chosen that all remain finite as Λ tends to infinity, and are plotted with Λ as variable. Table 2 gives the calculated values from which the curves were obtained. Graphs are also given, for various fixed values of Λ, with r/R as variable.

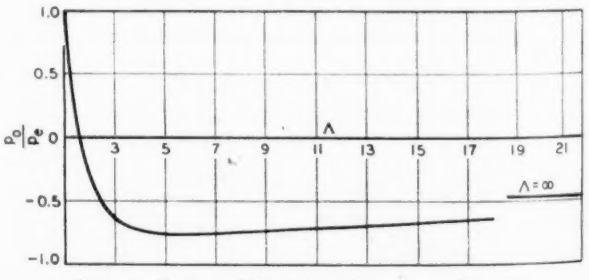

Fig. 2 Radial Membrane Stress at Center

It is convenient to discuss here limit situations for $\Lambda \to \infty$ and plot limit values of all quantities, though the mathematical discussion of these matters is given in the next section.[12]

Radial Membrane Stress. In Fig. 2 the curve for the quantity p_0/p_e is given to show the behavior of the radial membrane stress p_0 at the center of the plate in its dependence on Λ. The plate

[10] It is impractical for two reasons to choose values of π_0 and κ_0 more or less at random: After lengthy computations it can appear that two different choices for π_0 and κ_0 lead to nearly the same solution; the values of π_0 and κ_0 change with increasing Λ in rather unexpected ways, for example, π_0 changes sign, and κ_0 starts at zero for $\Lambda = 1$ and tends again to zero for large values of Λ.

[11] Figs. 2 and 6 give values of p_0/p_e and $\sigma_{b0}/p_e\sqrt{\Lambda}$. From these one derives the values $\pi_0 = (p_E/\eta^2 E)\Lambda p_0/p_e$ and $\kappa_0 = C\Lambda^{3/2}\sigma_{b0}/p_e\sqrt{\Lambda}$, where $C = (p_E/\eta^2 E)/6\gamma(1+\nu) = 1.76$ and $(p_E/\eta^2 E) = 4.24$.

[12] The earlier ones were obtained from the perturbation method. For $\Lambda = 1.57$ identical results were obtained using the power-series method.

is in a state of hydrostatic compression for $\Lambda = 1$, at which buckling just begins. With increase of Λ one expects p_0/p_e to decrease because of the buckling and consequent stretch of the middle surface. From the figure it is seen that p_0/p_e decreases rapidly and, what is surprising, eventually becomes negative,

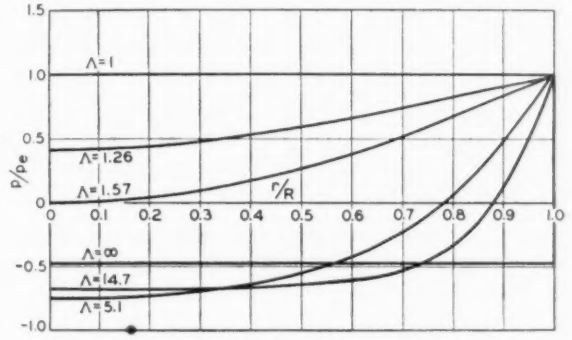

FIG. 3 RADIAL MEMBRANE STRESSES

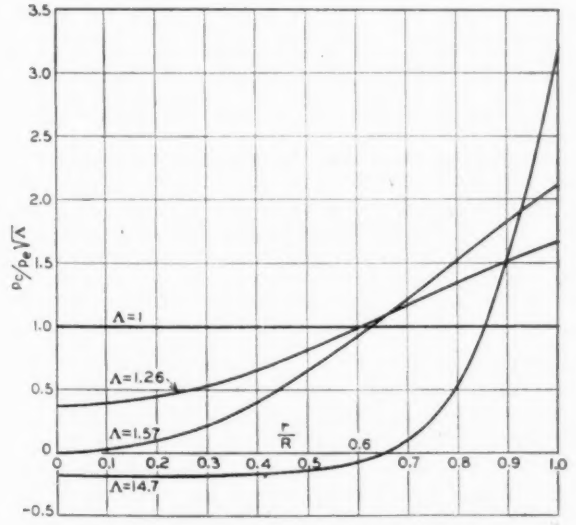

FIG. 4 CIRCUMFERENTIAL MEMBRANE STRESS

i.e., p_0 becomes a tensile stress. The transition occurs for the quite low value $\Lambda = 1.57$. For $\Lambda \sim 5.5$ the quantity p_0/p_e has an absolute minimum (—0.76); from this point on it increases slowly and attains the value —0.67 for $\Lambda = 14.7$. The asymptotic value for $\Lambda \to \infty$ is —0.47.

Fig. 3 shows curves for p/p_e as a function of r/R for various fixed values of Λ. The main feature of these curves is that for the higher values of Λ this quantity tends to become a negative constant over the central portion of the plate and then to rise rapidly to positive values in a strip near the edge. As will be shown in the next section, the width of this "boundary layer" tends to zero with increasing Λ. The curve marked $\Lambda = \infty$ indicates the limit curve for $\Lambda \to \infty$.

Maximum Stresses. Fig. 4 depicts the circumferential membrane stress p_c as a function of r/R for various fixed values of Λ. The values of p_c and of the radial membrane stress p are the same at the center of the plate (i.e., $p_{c0} = p_0$) because of symmetry, hence p_{c0} becomes negative beyond $\Lambda = 1.57$. The stress p_c increases much more rapidly than p toward the edge of the plate and for all values of Λ retains its maximum at the edge. These maxima (p_{c_e}) increase with Λ in higher degree than the maxima p_e of p: It was hence convenient to plot $p_c/p_e\sqrt{\Lambda}$ rather than p_c/p_e. For high values of Λ the curves indicate that p_c/p_e tends to become constant over an increasingly large portion of the plate. Since $p_{c0} = p_0$, it is clear that p_{c0}/p_e has the limit value —0.47.

Curves for the radial bending stress σ_b (actually $\sigma_b/p_e\sqrt{\Lambda}$) as a function of r/R for various values of Λ are shown by Fig. 5. For $\Lambda = 1$, when buckling just begins, $\sigma_b \equiv 0$. The maximum of σ_b is attained at the center until $\Lambda = 1.57$; up to this point the curves present no striking features. When Λ increases beyond 1.57, however, the point where p_b attains its maximum is no longer at the center, but shifts toward the edge of the plate. When $\Lambda = 2.01$, for example, the maximum is already beyond $r/R = 0.5$; for $\Lambda = 14.7$ the maximum occurs at $r/R = 0.87$. For large values of Λ, $\sigma_b/p_e\sqrt{\Lambda}$ at the center of the plate decreases rapidly and tends to zero as $\Lambda \to \infty$; it might be mentioned that the same is also true of the quantity σ_b/p_e at the center. With increasing Λ the high values of σ_b tend to be concentrated in a boundary layer.

The variation of $p_{c_e}/p_e\sqrt{\Lambda}$, $\sigma_{b0}/p_e\sqrt{\Lambda}$, and $\sigma_b \max/p_e\sqrt{\Lambda}$ with Λ is shown in Fig. 6. The limit values obtained by the asymptotic

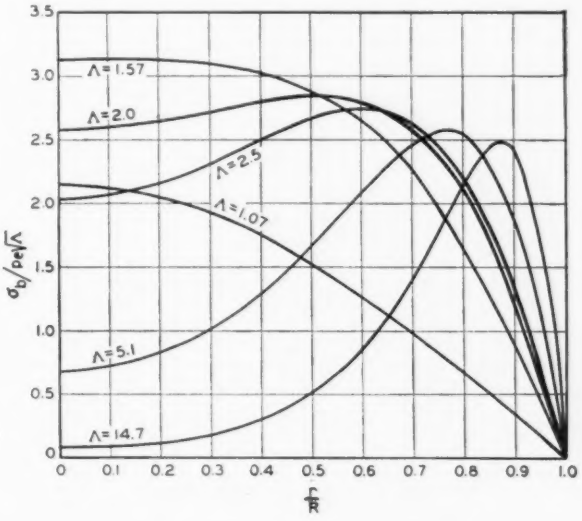

FIG. 5 RADIAL BENDING STRESS

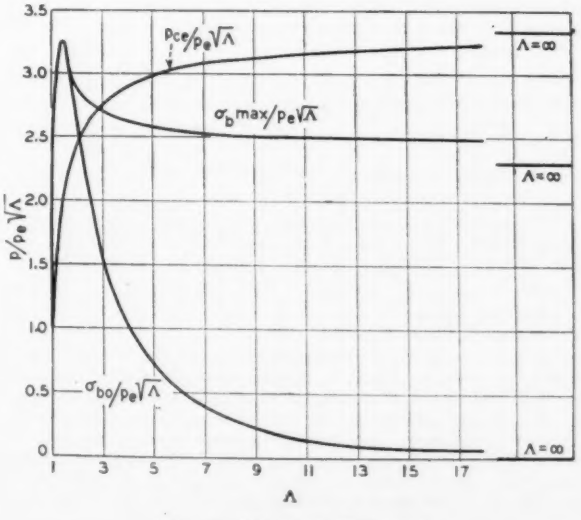

FIG. 6 MAXIMUM STRESSES

theory are also shown and the curves indicate clearly that these quantities really do tend to the limit values.

The circumferential bending stress σ_{bc} is not shown.[13] Its maximum is attained at the center and is the same as that of σ_b at this point up to $\Lambda = 1.57$; beyond this value of Λ, the maximum point also shifts toward the edge but the maximum value is always less than that of σ_b. Asymptotically $\sigma_{bc} = \nu\sigma_b$. Further, the maximum of the radial membrane stress p is always less than that of p_c. Hence, for design purposes, if the maximum-stress theory is used, only the stresses σ_b and p_c need be considered.[14] From $\Lambda = 3$ on, the circumferential membrane stress p_{cs} dominates.[15]

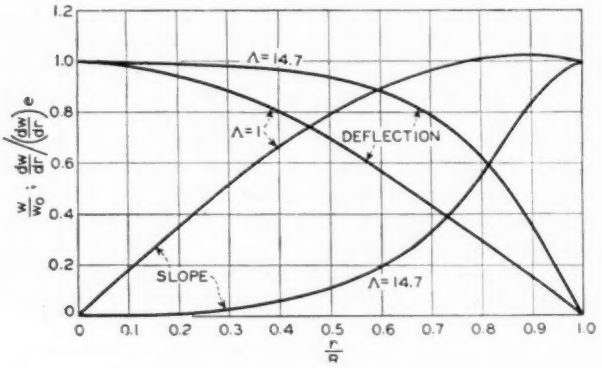

FIG. 7 SLOPE AND DEFLECTION

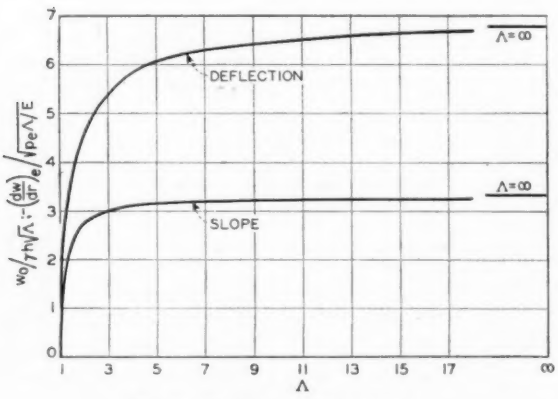

FIG. 8 SLOPE AND DEFLECTION

Slope and Deflection. In Figs. 7 and 8 the deflection w and the slope dw/dr are shown. In Fig. 7 the ratio of w and dw/dr to their maxima, i.e., w/w_0 and $(dw/dr)/(dw/dr)_e = rq/Rq_e$, are given as functions of r/R for the values $\Lambda = 1$ and $\Lambda = 14.7$. There is a quite perceptible flattening of the deflection curve for the higher values of Λ, accompanied by a tendency of the slope to approach zero in the central portion of the plate. Asymptotically the curve for w/w_0 would consist of two segments: a horizontal straight line up to the edge ($r/R = 1$) of the plate and a vertical line from it down to zero. Fig. 8 shows a rapid approach of the quantities $w_0/\gamma h\sqrt{\Lambda}$ and $-(dw/dr)_e/\sqrt{(p_e\Lambda/E)} = q_e/\sqrt{(p_e\Lambda/E)}$ to their asymptotic values.

Asymptotic Range. It is seen from the curves that the solutions from about $\Lambda = 5$ on do not change qualitatively; even quantitatively there is little change. Hence, for the range $\Lambda > 5$, which might be called the "asymptotic range," the solutions are at least roughly approximated by the asymptotic solution.

6—Limit State and Asymptotic Solution

As is seen from the curves, the deflection and stresses are nearly constant over a large portion of the plate when Λ becomes large and abrupt changes in all quantities occur in a narrow strip near the edge of the plate. In addition, the quantities p_0/p_e, $p_{ce}/p_e\sqrt{\Lambda}$, $\sigma_{be}/p_e\sqrt{\Lambda}$, etc., appear to approach finite limit values as Λ tends to infinity. It is possible to give a mathematical treatment of this limit process and obtain from it the limit values.

An asymptotic treatment of laterally loaded plates has been given by Hencky following A. Föppl (7, 4). Cf. also (1). It consists in omitting the terms referring to bending in the von Kármán equations (i.e., the left member of Equation [2]). One is tempted to apply an analogous treatment to the present problem, but this would lead to incorrect results. The procedure analogous to Hencky's would be as follows: Since $\Lambda = p_e/4.24\eta^2E$ it is clear that $\Lambda \to \infty$ if the slenderness ratio η tends to zero while p_e is held fixed. Upon allowing $\eta \to 0$ in the differential equations [8] and [9] one obtains

$$E^{-1}\Gamma p = q^2/2, \quad pq = 0 \ldots\ldots\ldots [29, 30]$$

the only nonsingular solution of which is $q \equiv 0$, $p \equiv$ const. If, then, this constant were identified with the edge value p_e, one would obtain as limit state a hydrostatic compression, which would clearly be wrong since the limit state appears rather to be one of constant tension. See Fig. 3. The error does not lie in the solution $q \equiv 0$, $p \equiv$ const but in the manner of fixing the constant. The sudden change in p from tension to compression that takes place across the boundary layer must be considered; the value of the constant under discussion is to be identified with the limit value of p at the inner edge of the boundary layer. Hence it can be found in this case only by an independent treatment of the boundary layer.[16]

The essential feature in the mathematical treatment of the boundary layer (as is also the case with Prandtl's boundary-layer theory for viscous flow) consists in stretching the scale with increasing Λ in such a way that the width of the boundary layer (measured in the new scale) does not shrink to zero. This can be done by introducing the new variable

$$\beta = (1 - r/R)\lambda, \quad 0 \leq \beta \leq \lambda, \text{ where } \lambda = (p_e/E)^{1/2}/\eta$$

It is necessary also to introduce new dependent variables which remain finite as $\Lambda \to \infty$. Such variables are found to be $P = p/p_e$ and $Q = q/\gamma\sqrt{(p_e/E)}$. Introducing the new variables into the differential Equations [8] and [9] and then allowing λ to tend to infinity, gives the differential equations

$$\frac{d^2P}{d\beta^2} = \frac{1}{2}Q^2, \quad \frac{d^2Q}{d\beta^2} + PQ = 0 \ldots\ldots [31, 32]$$

[13] The stress σ_{bc} is given by the formula

$$\sigma_{bc} = 6\gamma\eta E[\nu r q_r + (1 + \nu)q]$$

[14] The relative magnitudes of the stresses are here given for the case $\Lambda = 14.7$. The stresses at the edge ($r/R = 1$) where p_c is maximum, and at r/R where σ_b is maximum, are as follows

r/R	$p/p_e\sqrt{\Lambda}$	$\sigma_b/p_e\sqrt{\Lambda}$	$p_c/p_e\sqrt{\Lambda}$	$\sigma_{bc}/p_e\sqrt{\Lambda}$	$\tau_b/p_e\sqrt{\Lambda}$
1.0	0.3	0	3.2	0.7	1.8
0.87	0	2.5	1.2	1.4	1.2

The quantity τ_b is the horizontal shear stress due to bending. (τ_b is, as one expects, small and it vanishes asymptotically.) It is clear that the stress p should be combined with σ_b and the stress p_c with σ_{bc}. But, in any case, the stress p_c at the edge governs for $\Lambda = 14.7$.

[15] This is, however, not true in the case of the clamped plate, where the maximum of σ_b as well as of p_c is always attained at the edge. The authors have solved the asymptotic problem for this case and have found that in the limit $\sigma_{bs}/p_{cs} = 6\gamma = 1.8$; hence the bending stress governs.

[16] Hencky's method is, however, legitimate in his case where neither edge *compression* nor edge moment is prescribed.

The range of the variable β is obviously $0 \leq \beta \leq \infty$, where $\beta = 0$, $\beta = \infty$ correspond to the outer and inner edges of the boundary layer respectively. The boundary conditions become

$$P = 1, \quad dQ/d\beta = 0 \text{ for } \beta = 0$$

and regularity for $\beta = \infty$.

The authors have solved this nonlinear boundary-value problem and proved that its solution gives the limit values correctly (26).[17,18] From the functions P and Q thus obtained finite limit values were also found for all quantities discussed in the preceding section. In particular, $P(\infty) = -0.47$, which is the limit value for p/p_e at the inner edge of the boundary layer. Hence the constant $-0.47\ p_e$ is the one needed to complete the solution by the method of Hencky. Consequently it is proper to take -0.47 as the limit value for the ratio p_0/p_e, which refers to the value of p/p_e at the center of the plate.

Mathematically there is only one passage to the limit characterized by

$$\Lambda \to \infty \text{ or } p_e/\eta^2 E = p_e R^2/\gamma^2 h^2 E \to \infty \quad \ldots\ldots [33]$$

For a fixed plate (R and h fixed), this would require $p_e \to \infty$, implying infinitely high stress. If p_e is held fixed, one might consider a series of plates for which the slenderness ratio $\eta \to 0$; for example the radius R might be held fixed and the thickness h allowed to approach zero. In this case the governing stresses would tend to become infinite, as one sees from the limit relation

$$p_{c_e} \sim (3.33)p_e\sqrt{\Lambda} = 3.33\, p_e^{2/3}/(4.24)^{1/3}\eta E^{1/3} \to \infty \quad \ldots\ldots [34]$$

However, for a value of Λ as large as one pleases, plates could be designed for which stress and slope would be as small as necessary to insure the validity of the von Kármán equations. In order to see this let η and p_e tend to zero in such a way that $p_e/\eta^2 E \to \infty$ while $p_e/\eta E = \sqrt{(4.24\Lambda p_e/E)}$ remains sufficiently small; then it follows from the asymptotic formula $p_{c_e} \sim (3.33)p_e\sqrt{\Lambda}$ for the greatest stress and the formula $q_e \sim (3.33)\sqrt{(p_e\Lambda/E)}$ for the greatest slope (see Table 2), that p_{c_e} and q_e can be made as small as desired.

A valid objection on physical grounds to the application of our formulas for high values of Λ may well be raised: It is likely that there is a value of Λ for which the buckled state in its turn becomes unstable, and what might be called a "second buckling" sets in; such a second buckling would not, of course, possess the radial symmetry of the first buckled state. Rough calculations indicate, however, that the second buckling will probably not begin until Λ is somewhere in the asymptotic range ($\Lambda > 5$).

If one were to pursue the second buckling into its nonlinear range, it is likely that it would eventually also become instable and a "third buckling" ensue, and so on; that is, more and more wrinkles would appear at the edge of the plate. Various experimenters, working with rectangular plates, have found that the plates do become wrinkled near the edges (2, 3, 8, 12, 13, 18, 19). The authors feel that such wrinkles are to be explained as the result of a buckling of order higher than the first.

It is of interest to indicate the relation[19] between the authors' asymptotic results and the notion of effective width introduced by von Kármán for the rectangular plate which is simply supported on two opposite sides and subjected to a thrust at the other two sides. In spite of the obvious difference between the present case and that of von Kármán, it is nevertheless true that these results throw some light on the latter case and contribute to substantiate certain assumptions on which von Kármán bases the derivation of his formula. These assumptions concerning the stress distribution for high values of the thrust (or for small thickness) are as follows: 1 The stresses will be concentrated in a strip along the simply supported edge; and 2 the membrane stress on an element perpendicular to this strip rather than the bending stress will be the maximum stress. The same properties of the stress distribution are found mathematically for the present case of the simply supported circular plate with radial symmetry. It may be mentioned, however, that the stress distribution in the circular plate will not conform to property 2 if the plate is clamped.[15]

Von Kármán's formula can be considered as a relation between maximum and average value of the membrane stress on an element perpendicular to the boundary strip. In the present case the stress on an element perpendicular to the boundary strip is the circumferential membrane stress p_c. Its average value $\bar{p}_e$ is given by

$$\bar{p}_e = R^{-1}\int_0^R p_c dr = R^{-1}\int_0^R \frac{d}{dr}(rp)dr = p_e \quad \ldots\ldots [35]$$

From the asymptotic formula

$$p_{c_e}/p_e\sqrt{\Lambda} \to 3.3 \quad \ldots\ldots [36]$$

there results

$$(\bar{p}_c/\eta^2)/(p_{c_e}/\eta^2)^{2/3} \to 0.728 \quad \ldots\ldots [37][20]$$

In von Kármán's formula the power 1/2 takes the place of the power 2/3. A strong discrepancy was to be expected owing to the different shape of the plate, the different way in which the thrust is applied, and the different wave pattern that is assumed. The authors think it likely that the discrepancy is caused mostly by the different wave pattern. The wave pattern assumed in von Kármán's case probably corresponds to buckling of higher order than the first.

[17] In much the same manner the asymptotic solutions for the buckling of the clamped plate and the plate under edge moment were obtained. It may be of interest to note that the boundary-layer phenomenon occurs in these cases also.

[18] It is possible to apply a perturbation method in the neighborhood of $\lambda = \infty$ by expansions in powers of $1/\lambda$. The foregoing solution would constitute the first step in such a procedure. The authors have carried out the second step also (26).

[19] This relation is also discussed by von Kármán (25).

[20] This number was given incorrectly in (5). See reference (26).

A Short-Gage-Length Extensometer and Its Application to the Study of Crankshaft Stresses

By C. W. GADD[1] and T. C. VAN DEGRIFT,[2] DETROIT, MICH.

The mathematical methods of determining elastic stresses in machine elements, particularly those of irregular contour, may be excessively complex, so resort is frequently made to approximate calculations, which tend to lose accuracy while achieving simplicity. As a result a constant effort is made to supplement the mathematical treatment with experimental methods of studying stress. In this paper, the authors describe a short-gage-length extensometer and explain its application in the determination of crankshaft stresses. This instrument meets the requirement of convenience in operation, which is so essential in assuring that it will be used for the study of localized stresses.

Introduction

A CONSIDERATION of the elastic stresses which a machine element is likely to encounter under operation is recognized as an important factor in its design. However, it is a task which, in the case of parts of irregular contour, may require mathematical methods of excessive complexity, and is therefore often attempted by inadequate approximate calculations which lose accuracy while achieving simplicity. Errors of considerable importance can thus result, particularly if the design is entirely new; and little or no background exists upon which to check theoretical calculations or build empirical ones. Furthermore, with the necessity in certain fields, for example, that of aircraft engines, of arriving as closely as possible at the ideal design, from the standpoint of employing a minimum of material consistent with adequate strength, it becomes increasingly important to determine stresses as accurately as possible.

Thus, there is a constant effort to supplement mathematical with experimental methods of studying stresses. In order to be of practical value in industry, however, the latter must be sufficiently convenient in operation that the engineer will actually use them in preference to a simplified calculation, or even a trial-and-error method. This requirement has seriously limited the use of measuring instruments designed for the study of localized stresses. An instrument is described in this paper which, it is felt, does to a great extent meet such a requirement.

Ordinarily no experimental method, short of actual service tests, can give the ultimate answer as to whether the strength of a newly designed part will be adequate, particularly if only a low factor of safety is desired. It is generally realized that other factors such as the condition of the surface, the material, residual stresses, and others, in addition to the actual shape of the part, influence importantly its strength. An instrument which can aid in the study of stress distribution due to shape of the part can, however, be of definite value in the following ways:

1 It can reduce the uncertainty in an original design by performing one step, namely, that of ascertaining stress distribution from assumed loads on the part.

2 It can provide a check upon the relative merit in alternate designs, when it is desired that a part, which has been failing, be improved.

The foregoing of course presupposes some knowledge of the nature of working loads imposed upon the part. These, if complex, may provide the source of greatest error in any stress investigation, whether mathematical or experimental. In checking alternative designs, however, it has usually been found possible to learn enough of the nature of actual loads to permit a valid check as to whether the alternate design is superior to the original, although the exact degree of improvement may be uncertain.

A program of stress investigation with the aid of the extensometer has usually been as follows:

1 The external loads on, or distortions of, the part in question are first estimated as accurately as possible by theoretical methods or, where feasible, by study of similar parts under operation with available instrumentation.

2 Static-loading devices are set up and stress-distribution traverses are made. It has been found desirable to employ "Stresscoat" strain-indicating lacquer in conjunction with the extensometer, both for the purpose of localizing quickly the analysis in the more dangerously stressed regions, and for determining the directions of the principal strains at these regions.

3 If it is desired that actual operating stresses be checked, as an aid in further study, after a model of the engine or other mechanism containing the part in question is in operation, this may be done by placing a dynamic strain gage at certain accessible points on the part, thus establishing a "scale" for the complete stress-distribution curves found statically.

Description of Extensometer

Principle of Operation. Operation of the gage is by means of

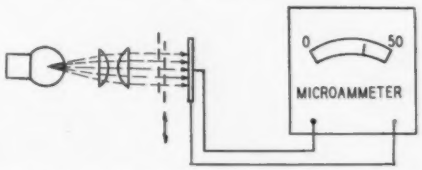

Fig. 1 Operation of Extensometer Optical System

(1) a simple mechanical lever integral with one of the gage points, and (2) a pair of gratings of alternate transparent and opaque bands, which intercept a collimated beam of light rays directed on a photocell. The mechanical stage is coupled directly to one of

Presented at the Annual Meeting, New York, N. Y., December 1–5, 1941, of The American Society of Mechanical Engineers.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until April 10, 1942, for publication at a later date. Discussion received after the closing date will be returned.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

the gratings, while the other remains fixed, except when making necessary adjustments prior to applying the load to the specimen and checking a stress. Thus, when the specimen is strained, the gratings move relative to one another in such a manner that light falling on the cell varies in proportion to the strain.

The variation in current generated by the cell is, in turn, indicated on a microammeter connected directly with the cell. Other data pertaining to the instrument are as follows:

Height, in	$2^1/_4$
Weight, oz	$^1/_2$
Gage lengths used (separate instruments), in	$^1/_{16}$, $^1/_8$, and $^1/_4$
Magnification:	
Mechanical	25:1
Optical	1200:1
Over-all	30,000:1
Strain-indicating scale	50-Mu-a ammeter with $6^1/_4$-in. scale. (Usable or linear range of gage output approximately 20 mu-a)
Power source for lamp	Voltage-regulating circuit connected in 110-v a-c line, for furnishing power to the 3.8-v extensometer lamp
Method of calibration	Standard tensile specimen mounted in testing machine

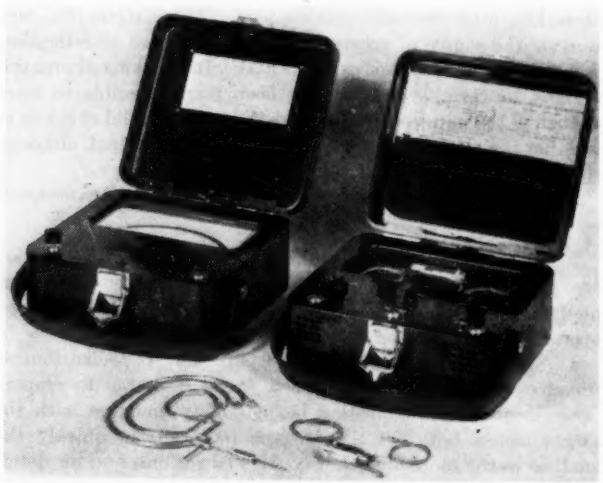

FIG. 2 MICROAMMETER, POWER UNIT, CLAMPS, AND EXTENSOMETER

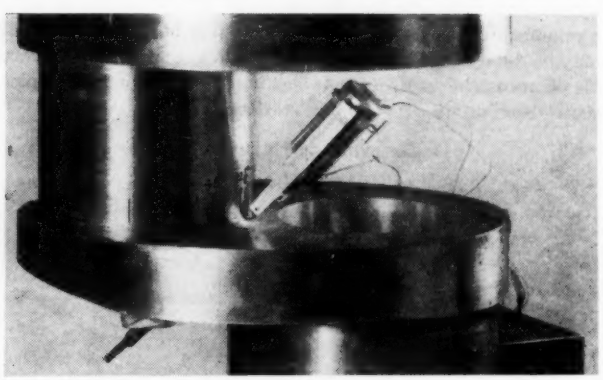

FIG. 3 EXTENSOMETER MOUNTED IN CRANKPIN FILLET

The 30,000:1 magnification cited, which results from the use of gratings of 120 lines per in. and the $6^1/_4$-in. microammeter scale, has been found satisfactory for all work done with the gages thus far.

Mounting the Gage. The gage is pivoted midway between the points, and mounted by one of the two methods shown in Fig. 4. The C-clamps are made of stock which can be bent with the fingers to various shapes. The second method is used where access cannot be had to the opposite side of the work.

No prick-punch marks are used with the gage. The force of approximately 1 lb required to hold the gage against the work provides a frictional force at the points sufficiently great to operate the gage.

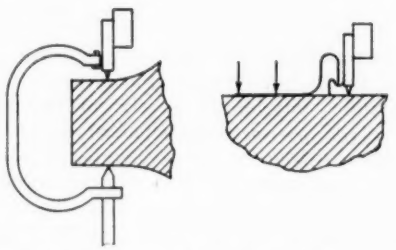

FIG. 4 METHODS OF MOUNTING THE INSTRUMENT

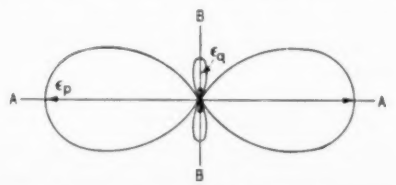

FIG. 5 STRAIN DIAGRAM IN POLAR CO-ORDINATES

Interpretation of Measurements. This phase of the work is considered in detail elsewhere in the literature; it will suffice here only to point out a variation from ordinary procedure, necessary when a short gage length is employed. Whereas, with a long gage length, a complete determination of the state of surface stress may be obtained by making measurements at a minimum of three known angles, this procedure is inadvisable if maximum accuracy is to be assured with a $^1/_{16}$-in. gage length, due to inaccurate maintenance of the angular relationship of the measurements. The alternative method for eliminating this inaccuracy consists, first, in making a sufficient number of checks in the general direction of AA, Fig. 5, to establish as accurately as is desired the value of the maximum principal strain ϵ_p. (Usually its direction may be estimated approximately before making any measurements.) Second, checks are made in the direction BB, at right angles to AA, for obtaining the minimum principal strain ϵ_q. Knowing the two principal strains, the formulas

$$\sigma_p = \frac{E}{1 - \mu^2}(\epsilon_p + \mu\epsilon_q)$$

$$\sigma_q = \frac{E}{1 - \mu^2}(\epsilon_q + \mu\epsilon_p)$$

for converting to stress are applied, where E = modulus of elasticity; σ_p and σ_q = principal stresses; ϵ_p and ϵ_q = principal strains; μ = Poisson's ratio.

To eliminate the foregoing computation for each point, however, a uniform-scale-alignment chart may be employed.

CRANKSHAFT-STRESS MEASUREMENTS

As an example of a practical application of the strain gage, an analysis of certain phases of the problem of crankshaft stresses will be given. It should be emphasized that this analysis is not complete, but that it is rather an attempt to learn the effect upon the magnitude of stress concentration in a shaft of only a

few of the design variables. A partial analysis of this kind has been found useful in two ways (1) as a method of improving an existing design, and (2) as an indication of the trends of shaft strength as functions of certain variables which are taken into consideration in an original design.

Torsional Stress

Critical Regions in Crank Throw. The critical region for a crank throw in torsion ordinarily occurs in the crankpin fillet, somewhat below center, as shown at *A*, Fig. 6, and with the principal planes oriented at approximately 45 deg with the fillet. A similar critical region also exists in the journal fillet which, however, is not usually as dangerous as the former, because of the heavier construction customarily employed in the journal. When the crank throw is left solid, high stresses are confined to these regions.

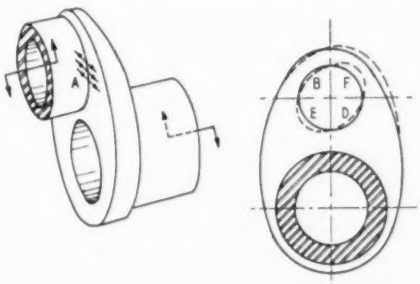

Fig. 6 Location of Critical Torsional Stress, and Distortion of Hollow Crankpin Under Torsion

Fig. 7 Crankpin Arrangement

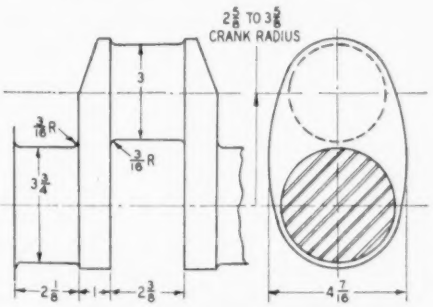

Fig. 8 Dimensions of Crank Throw

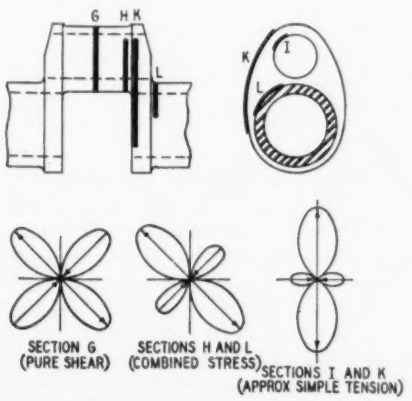

Fig. 9 Location of Torsional Strain Traverses, and Typical Strain Rosettes

If, in addition, the crankpins and journals are bored (for the purpose of lightening the shaft), a partial collapse of the ends of the pins and journals occurs, as shown, which produces concentrations of tensile stress at *B* and *D*, and compressive stress at *E* and *F*, with the principal stress oriented parallel to the edge of the lightening hole. (At the opposite end of the throw, distortion of the cheek is in the opposite direction, and points of tension and compression are consequently reversed.) Again, if heavier construction is employed in the journal, stresses are greater in the pin than in the journal, and are greater at *B* than at *D*.

In the case of hollow shafts, although stresses in the crankpin fillets ordinarily are more dangerous than at the edge of the lightening holes, it is possible, if the holes are enlarged sufficiently, to obtain stresses at their edges which are more severe than those in the fillets.

Method of Loading the Shafts in Torsion. All torsional measurements were made on 6-throw 7-main-bearing shafts, with the conventional 120-deg crank arrangement shown in Fig. 7. Dimensions of the throw are given in Fig. 8. The shafts were mounted on rollers 3 in. diam × ¾ in. wide, three of which contacted the shaft at each journal. In turn, these were mounted with a rigidity such that they partially constrained the journals from transverse motion as the torque was applied. The degree of constraint imposed upon the shaft by the crankcase of course influences the state of stress in the shaft, and, as in any experimental stress investigation, the location of most severely stressed points in the laboratory model should, wherever possible, be checked against the location of nuclei of field failures, if there is any question as to the validity of method of loading the model in the laboratory.

Stress-distribution traverses were made at sections *G*, *H*, *I*, *K*, and *L* of the crank throws, as shown in Fig. 9. At the mid-section of the crankpin, section *G*, contraflexure occurred, and the strain rosettes were those of pure shear, such as would be found in a straight shaft in torsion. At points around sections *H* or *L* in the pin and journal fillets, respectively, the strain patterns indicated shear, combined with a varying amount of normal stress, but with the principal planes still at approximately 45 deg. Strain along sections *K* and *I*, the edges of the cheek and crankpin lightening hole, respectively, approximated simple tension.

Strains were predominantly tensile on one side of the cheek (the forward side of the left-hand illustration in Fig. 6) and compressive on the other, but reversed when the direction of the torque was reversed.

Preliminary measurements on several shafts in torsion indicated two sources of scatter of the results:

1 A variation, usually no greater than 6 per cent, existed between results at identical points on different shafts of the same design. This was considered normal, and due to variations in material, machining, or measurement.

2 However, a type of scatter of much larger proportions was found in the stress-concentration values at identical critical regions of different cheeks of the same shaft, and at opposite sides of the same cheeks. Apparently stress concentration in torsion was a function of orientation of the crank throws adjacent to the one under consideration. This latter scatter reached approximately 30 per cent in the shear stress at the points of maximum crankpin-fillet concentration (point *A*, Fig. 6). An inspection of this scatter indicated that, of the twenty-four such critical localities on the 6-throw shaft, eight of these, situated such that the adjacent throw was at 240 deg (for example, the left side of the first cheek of throw No. 2, Fig. 7) were consistently more highly stressed than the others. The least highly stressed cheeks

were the middle ones, which are located at 0 deg relative to one another.

The stress-concentration factor in torsion in a conventional crankshaft, employing identical crank throws and symmetrical cheeks, therefore, cannot be stated as a constant for a given crank-throw design, but is in addition a function of crank arrangement. Stress-distribution curves, given subsequently, were taken from the right-hand side of the second cheek of throw No. 2,

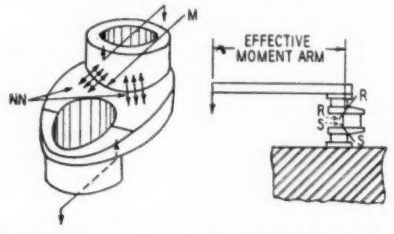

FIG. 10 LOCATION OF CRITICAL BENDING STRESSES

FIG. 11 METHOD OF APPLYING BENDING MOMENT

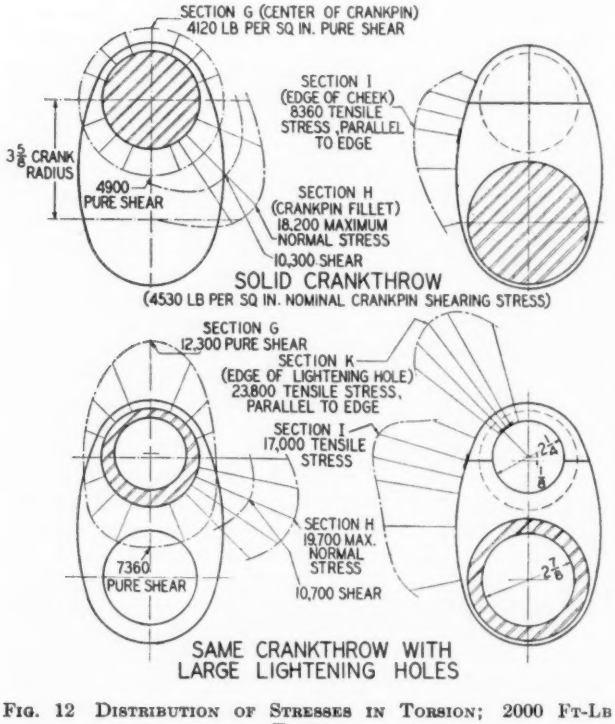

FIG. 12 DISTRIBUTION OF STRESSES IN TORSION; 2000 FT-LB TORQUE

in Fig. 7, which was one of the eight more highly stressed areas in the shaft.

BENDING STRESS

Only distortion of the type ordinarily encountered when resonant bending vibration is present, or when an overhung load exerts a reversed bending couple at the end of the shaft, will be considered. Distortion of this type was simulated by bending a single throw, flanged at the ends, with a beam as shown in Fig. 11. Greatest deflection, and highest stresses, for a given moment, were found to occur when the bending moment was applied in the plane of the crank throw.

As would be expected, the abrupt change in section at the journal and pin fillets, at sections *RR* and *SS*, resulted in highest concentrations of stress here. However, the nature of these concentrations depended in a large measure upon whether or not lightening holes were present. If journals and pins were solid, stress reached a maximum at the center, point *M*, Fig. 10, whereas if they were bored, stress at the center receded and a pair of peaks *NN* formed.

Bending throughout the short cheek section between pin and journal was found to differ from that of a simple beam, in that the constraint of the pin and journal annulled anticlastic curvature of the cheek, with the result that strain laterally was very nearly zero, and the principal stress in the direction shown in Fig. 10 was larger by the factor $1/(1 - \mu^2)$ than would be the case of simple bending. This condition held at the points of highest stress in both journal and crankpin fillets.

STRESS-DISTRIBUTION CURVES

In Figs. 12 and 13 are plotted sample distribution curves taken on solid crank throws of the dimensions shown in Fig. 8, before and after boring large lightening holes in the crankpin and journals. Included with both sets are nominal calculated stress values upon which stress-concentration factors may be based. In torsion, stress is calculated assuming the crankpin as a shaft in simple torsion. In bending, the calculation assumes a beam of the same cross section as the cheek, subjected to simple bending

EFFECT OF DESIGN VARIATIONS

(*a*) Crank Radius:

Holding other dimensions constant, the crank radius of the crank throw, shown in Fig. 8, was varied from $2^5/_8$ to $3^5/_8$ in. in three steps. This range covered typical degrees of "overlap" between journal and pin normally employed in practice.

As seen in Fig. 15 the solid shaft is strengthened considerably for a given bending load by overlapping the journal and crankpin. In the direction of increasing crank radius, stress concentrations approach constant values, because the pin and journal become isolated from one another and each is stressed independently of the other.

In torsion the trend is similar, but the percentage of variation in stress concentration is much less.

Although both in bending and in torsion, the use of a larger crank radius tends to weaken a solid crank throw, this trend does not necessarily obtain in particular designs of hollow crank throws, since, as will be made clear later, the proximity of a lightening hole to the region of high fillet stress constitutes another variable which can also exert an important influence upon the degree of stress concentration.

(*b*) Lightening Holes in Journal and Crankpin:

Stress Due to Bending. Concentration of stress in the fillets, resulting from a bending moment, is affected by the presence of lightening holes in two ways. Considering the critical journal-fillet stress, its value will rise according to curve *T*, Fig. 16, as the journal bore is enlarged, while holding the crankpin bore at an arbitrary diameter. On the other hand, if the journal bore is held, while varying the crankpin bore, the journal-fillet stress, will, instead of rising continuously, pass through a minimum or optimum value at a particular diameter of crankpin bore, as indicated by curve *U*. This minimum value occurs as the stress at the center of the cheek, point *M*, Fig. 10, is relieved by the crankpin lightening hole, and two points of concentration *NN* at either side appear in its place. If both pin and journal bores are enlarged simultaneously, curve *V* will result, with the optimum value still appearing with the same diameter of crankpin bore.

These same general trends hold for crankpin-fillet stress.

As a specific illustration of these trends, the results of measurements on the same three throws previously used, with each of the

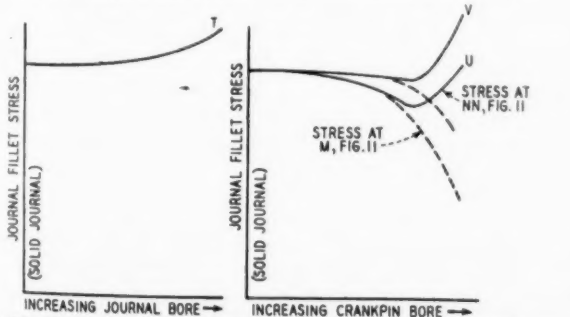

FIG. 16 EFFECT OF LIGHTENING HOLES ON JOURNAL-FILLET STRESS CONCENTRATION IN BENDING

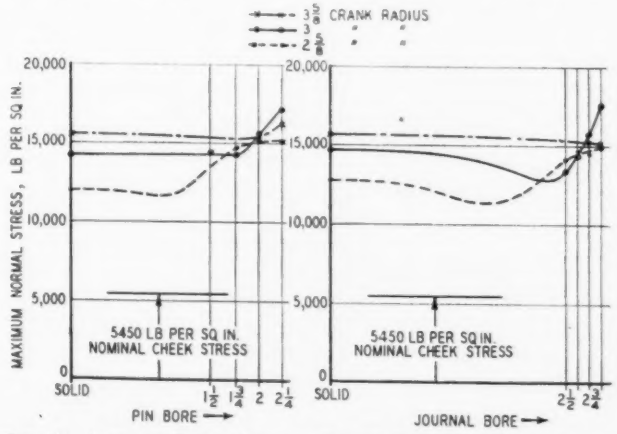

FIG. 17 JOURNAL-FILLET STRESS IN BENDING VERSUS LIGHTENING-HOLE SIZE; 336 FT-LB

FIG. 18 CRANKPIN-FILLET STRESS IN BENDING VERSUS LIGHTENING-HOLE SIZE; 336 FT-LB

following stages of lightening hole enlargement, will be given:

Stage No. 1; solid journal and solid crankpin
Stage No. 2; 2½ journal bore, 1½ crankpin bore
Stage No. 3; 2⅝ journal bore, 1¾ crankpin bore
Stage No. 4; 2¾ journal bore, 2 crankpin bore
Stage No. 5; 2⅞ journal bore, 2¼ crankpin bore

In each case, crankpin bores were located ⅛ in. outside concentricity with the outside diameter of the pin. In boring the throw of 2⅝ in. radius, straight bores were used until interference occurred with the bearing surfaces; from here on shoulders were left, as shown in Fig. 14.

Stresses due to bending for each of these stages are plotted in Figs. 17 and 18. In the case of the throw having the largest crank radius ($3^5/_8$ in.), it is seen that the lightening holes could not be enlarged sufficiently to affect bending stress in the fillets appreciably. Accomplishment of the latter would require removal of metal closer to the fillets, as at W, Fig. 14.[3]

Stress Due to Torsion. The influence of lightening holes upon torsional stresses is illustrated in the following two figures. Here again, stresses in the solid throws of shortest radius are least, but, with the introduction of lightening holes, the trend reverses. Furthermore, it is again possible, with the exception this time of the throw of shortest radius, to use an optimum lightening-hole size, such that a deviation either way aggravates the fillet stress.

[3] Mention is made of the expedient of removing metal, in effect, to produce a larger fillet radius in "Spannungsverteilung in Konstruktionselementen," by E. Lehr, V.D.I. Verlag, Berlin, 1934, p. 56.

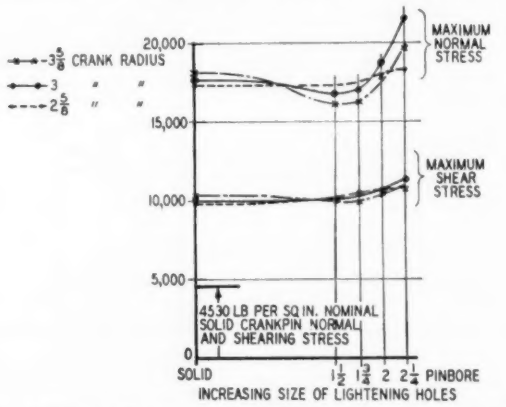

FIG. 19 CRANKPIN-FILLET STRESS IN TORSION VERSUS LIGHTENING-HOLE SIZE; 2000 LB TORQUE

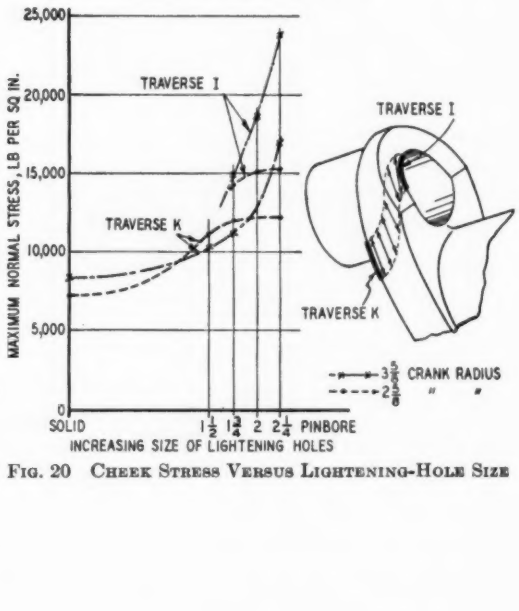

FIG. 20 CHEEK STRESS VERSUS LIGHTENING-HOLE SIZE

Fig. 20 illustrates another observation which can be made from the torsional measurements. Here are plotted the trends of maximum cheek stress against lightening-hole size. It is seen that, in contrast to fillet stress, the cheek stresses rise rapidly as the lightening holes are enlarged. As this is done, resulting distortion of the cheek produces a region of high tensile stress, extending around the cheek as shown, but with highest stresses at the edges I and K. If the crankpin lightening hole is enlarged sufficiently, stress at its edge I can become more severe than in the fillet. Thus, while it is not necessary to exercise care in providing fatigue-resisting cheek surfaces in manufacturing a heavy shaft, as in automotive practice, such a precaution becomes important in a lightweight, hollow one.

(*c*) Effect of Shoulders in Lightening Holes:

As was mentioned previously, shoulders were left in the lightening holes of the throw having a crank radius of $2^5/_8$ in., as illustrated in Fig. 14, in enlarging them beyond the point of interference with the bearing surfaces. As soon as this is done, the curves of critical stresses versus increasing lightening-hole diameter are seen to level off. Thus the leaving of a shoulder at the ends of the hole (sometimes used in aircraft practice), constitutes a means of preserving optimum design where it is needed while removing excess metal where it is not needed.

COMBINED STRESS

No attempt has been made in this analysis to combine bending with torsional loads. Thus far, it has been considered advisable to deal with each separately, according to the requirements of a particular problem, and, if both are critical, to look for design changes which do not increase bending strength at the expense of torsional strength, or vice versa.

CONVERSION CONSTANTS

Constants for conversion of the strain measurements into stresses were determined from strain measurements, made with the $^1/_{16}$-in. extensometer, on A.S.T.M. tensile-test specimens cut from the forged steel from which the shafts were made. These were as follows:

Modulus of elasticity = 29,500,000
Poisson's ratio = 0.300

All measurements were taken with the $^1/_{16}$-in-gage-length extensometer. In making fillet measurements, the gage was placed at several inclinations with respect to the crankshaft axis at every location, in order to determine the most severe stresses present.

Measurement of Latent Heat by the Gas-Current Method

By J. A. GOFF[1] and J. B. HUNTER,[2] PHILADELPHIA, PA.

The gas-current method of measuring latent heat appears to possess important advantages over other calorimetric methods. Preliminary results have been derived from a co-operative investigation carried out by the American Society of Heating and Ventilating Engineers and the Towne Scientific School, University of Pennsylvania, in which sufficiently reliable values of the interaction constant for air-and-water-vapor mixtures have been determined to permit an adequate thermodynamic analysis of the gas-current method. The present paper is devoted to the development of this analysis and its application to the reduction of certain experimental data recently obtained by one of the authors. The apparatus and method of conducting the experiments are also described.

Introduction

IN THE gas-current method of measuring latent heat, a steady stream of an indifferent gas is bubbled through, or passed over, the liquid to be investigated in an adiabatic calorimeter. Energy is supplied electrically at a constant measured rate in order to compensate the drop in temperature which would otherwise occur due to evaporation. The gas stream is brought to the temperature of the liquid before being admitted into the calorimeter. The rate of flow is continuously adjusted during test to maintain the temperature of the liquid constant and as nearly as possible equal to that of the surrounding bath. This not only eliminates heat leak into or out of the calorimeter, but also insures that the gas stream leaves the calorimeter with the same temperature as that of the liquid. The gas stream leaving the calorimeter contains vapor of the liquid. This is subsequently removed, usually by chemical means, over a measured period of time, and accurately weighed. Consequently, since the rate at which energy is supplied to the calorimeter is accurately known, the ratio of energy supplied to liquid evaporated, under conditions of constant temperature and constant total pressure, is easily computed.

The gas-current method appears to possess important advantages over other calorimetric methods. In the first place, it permits investigation over a range of temperature below the normal boiling point of the liquid, without requiring operation below atmospheric pressure. Thus the method permits measurements of latent heat at, or near, atmospheric temperature and atmospheric pressure (conditions most favorable to accurate calorimetry) in the case of liquids the normal boiling points of which may be well above atmospheric temperature. In the second place, the apparatus is comparatively simple and inexpensive, since glass construction can be used throughout. The method is particularly suitable for measurements on aqueous solutions of nonvolatile solutes.

The gas-current method seems to have been first employed successfully by A. W. Smith (1)[3] for measurement of the latent heat of pure water at five temperatures below 100 C. While Smith's experimental procedure is open to criticism in several important respects, and his results do not exhibit a high degree of consistency and reproducibility, nevertheless, his average values are lower than the values of latent heat recently reported by the National Bureau of Standards (2), as they should be for a reason which it is the principal object of this paper to explain. A completely satisfactory explanation must take into account the effect of intermolecular forces, particularly those of interaction between air and water vapor. Until recently no reliable data on the extent of this interaction have been available.

Preliminary results of the co-operative investigation between the American Society of Heating and Ventilating Engineers and the Towne Scientific School, University of Pennsylvania, have recently yielded sufficiently reliable values of the interaction constant for air-and-water-vapor mixtures to permit an adequate thermodynamic analysis of the gas-current method, at any rate as it applies to aqueous solutions of nonvolatile solutes in which the indifferent gas is dry carbon-dioxide-free air. These results are to be published shortly (3), and are described in more detail in the doctoral dissertation of A. C. Bates (4), on file in the Towne Scientific School library. The principal objective of the present paper is to develop the thermodynamic analysis and apply it to the reduction of certain experimental data recently obtained by one of the authors and which will form the basis of a dissertation to be submitted to the faculty of the Graduate School of Arts and Sciences, University of Pennsylvania, in partial fulfillment of the requirements for the doctorate in chemical engineering.

Thermodynamic Theory

Fig. 1 shows the flow diagram to which the following thermodynamic analysis applies. It is assumed from the start that:

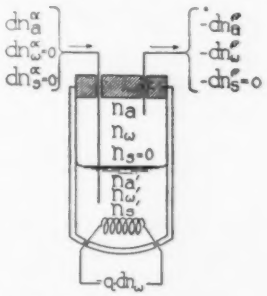

FIG. 1 FLOW DIAGRAM

1 The entering gas stream is dry CO_2-free air (subscript a) containing no water ($dn_\omega^\alpha = 0$) and no salt ($dn_s^\alpha = 0$).

[1] Dean, Towne Scientific School, University of Pennsylvania. Mem. A.S.M.E.

[2] Assistant Instructor in Chemistry and Chemical Engineering, Towne Scientific School, University of Pennsylvania.

Presented at the National Meeting of the Applied Mechanics Division, Philadelphia, Pa., June 20–21, 1941, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until April 10, 1942, for publication at a later date. Discussion received after the closing date will be returned.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

[3] Numbers in parentheses refer to the Bibliography at the end of the paper.

2 Concentration of salt in the vapor phase is entirely negligible ($n_s = 0$) and there is none in the leaving gas stream ($dn_s^\beta = 0$).

3 The temperatures of entering and leaving streams are the same and equal to that of the calorimeter contents which is constant.

4 The pressure is uniform throughout and constant.

5 The quantity of water evaporated and the consequent change in relative composition of the calorimeter contents are so small as to justify the use of mean values for partial molal volumes, energies, and enthalpies.

With the foregoing assumptions, the equations expressing conservation of matter are

for the air

$$dn_a^\alpha + dn_a' + dn_a + dn_a^\beta = 0; \quad [1a]$$

for the water

$$0 + dn_w' + dn_w + dn_w^\beta = 0; \quad [1b]$$

for the salt

$$0 + dn_s' + 0 + 0 = 0. \quad [1c]$$

The equation expressing constancy of the calorimeter volume is

$$\bar{V}_a' \cdot dn_a' + \bar{V}_w' \cdot dn_w' + \bar{V}_s' \cdot dn_s' + \bar{V}_a \cdot dn_a + \bar{V}_w \cdot dn_w = 0 \quad [2]$$

where the bar denotes differentiation with respect to the component designated by the subscript, at constant temperature, constant pressure, and constant weights of all other components. In other words, the bar specifies partial molal quantities for which mean values are to be taken in accordance with assumption 5. Finally, the equation expressing conservation of energy (no heat leak) is

$$h_a^\alpha dn_a^\alpha + \bar{H}_a^\beta dn_a^\beta + (\bar{H}_w^\beta - q) dn_w^\beta + \bar{U}_a' dn_a' + \bar{U}_w' dn_w' + \bar{U}_s' dn_s' + \bar{U}_a \cdot dn_a + \bar{U}_w \cdot dn_w = 0 \quad [3]$$

where h_a^α denotes the specific enthalpy of the entering air stream, and where it is to be noticed that q denotes the energy supplied electrically to the calorimeter per mol of water evaporated.

In the foregoing five equations, there appear eight differentials of type dn which must be eliminated, if a relation involving only thermodynamic properties is to be derived. For this purpose, therefore, three additional equations are required. One is obtained by assuming no appreciable accumulation of air in the liquid phase; that is

$$dn_a' = 0 \quad [4]$$

and two more are obtained by assuming that the relative composition of the vapor phase is constant and equal to that of the leaving stream; that is

$$\frac{dn_a}{dn_w} = \frac{n_a}{n_w} = \frac{dn_a^\beta}{dn_w^\beta} \quad [5]$$

However, with temperature, pressure, and relative composition the same in the vapor phase within the calorimeter as in the leaving stream, the following relations must hold

$$\bar{H}_a^\beta = \bar{H}_a \text{ and } \bar{H}_w^\beta = \bar{H}_w \quad [6]$$

Carrying out the desired elimination and, at the same time, eliminating internal energies in favor of enthalpies by means of the defining equation $H = U + PV$, the final result is

$$\bar{H}_w - \bar{H}_w' = q + (h_a^\alpha - \bar{H}_a) \frac{n_a}{n_w} - \frac{n_w \bar{V}_w'}{(n_a + n_w)v} \cdot q \quad [7]$$

where v denotes the specific volume of the vapor phase. It is by means of Equation [7] that data obtained by the gas-current method are to be reduced. The equation applies equally well to aqueous solutions of nonvolatile solutes and to pure liquids.

Pure Water

The data to be reported in this paper are on pure water. Although the ultimate objective of the experiments was information regarding certain aqueous solutions, pure water was used for calibrating the apparatus, since accurate values of the latent heat of water are available for comparison (2).

In the case of pure water, the partial molal quantities $\bar{H}_w'$, $\bar{V}_w'$ differ negligibly from the corresponding specific quantities h_w', v_w' since the concentration of dissolved air in the liquid phase is so small as to make it behave like an ideal solution (5). Thus, the application of Equation [7] reduces to the evaluation of the partial molal quanties $\bar{H}_w$, $\bar{H}_a$ and the specific volume v of the vapor phase, taking into account the effect of intermolecular forces which, though small, are nevertheless significant.

The starting point is the prediction of statistical mechanics (6) that at sufficiently low pressures

$$Pv = RT - [A_{aa}x^2 + 2A_{aw}x(1-x) + A_{ww}(1-x)^2]P \quad [8]$$

where

P = observed pressure
v = specific volume (volume per mol)
A_{aa} = second virial coefficient for air, a known temperature function
A_{ww} = second virial coefficient for water vapor, a known temperature function
A_{aw} = interaction constant, provisional values of which are now available
x = mol-fraction of dry air; namely, $n_a/(n_a + n_w)$

From Equation [8] may first be derived expressions for the partial molal enthalpies, although in this derivation a further prediction of statistical mechanics must also be used; namely, that at zero pressure the total enthalpy is the sum of separate contributions from the two constituents. The desired expressions are

$$\bar{H}_w = h_w^0 + [x^2 B - B_{ww}]P \quad [9a]$$

$$\bar{H}_a = h_a^0 + [(1-x)^2 B - B_{aa}]P \quad [9b]$$

where

$$B = B_{aa} - 2B_{aw} + B_{ww} \quad [9c]$$

and h_w^0, h_a^0 denote zero-pressure specific enthalpies; also where, for example

$$B_{aw} = -T^2 \frac{d(A_{aw}/T)}{dT} \quad [9d]$$

Introducing the saturation pressure of pure water p_s, a known temperature function, Equation [9a] becomes

$$\bar{H}_w = h_w^{sat} - B_{ww}(P - p_s) + x^2 B \cdot P \quad [10a]$$

while, applying Equation [9b] to air alone for the purpose of eliminating h_a^0

$$\bar{H}_a = h_a^\alpha + (1-x)^2 B \cdot P \quad [10b]$$

Finally, putting Equations [10a] and [10b] into Equation [7] this becomes

$$r - q = B_{ww}(P - p_s) - x \cdot B \cdot P - (1-x)\frac{v_w'}{v} \cdot q \quad [11]$$

where r denotes the latent heat of pure water.

TABLE 1 TEMPERATURE FUNCTIONS IN EQUATIONS [8] AND [9]

deg C	A_{aa}/RT (cm³ per kg)	B_{aa}/RT (cm³ per kg)	A_{ww}/RT (cm³ per kg)	B_{ww}/RT (cm³ per kg)	B/RT (cm³ per kg)
0	0.000578	0.00334	0.09005	0.6149	0.5719
5	0.000519	0.00317	0.07964	0.5356	0.4983
10	0.000464	0.00301	0.07072	0.4679	0.4356
15	0.000412	0.00287	0.06305	0.4101	0.3820
20	0.000364	0.00273	0.05642	0.3604	0.3359
25	0.000319	0.00260	0.05070	0.3178	0.2964
30	0.000277	0.00247	0.04573	0.2811	0.2623

In writing r for $h_w^{sat} - \overline{H}_w'$ and v_w for $\overline{V}_w'$ it has been assumed that the concentration of dissolved air in the liquid phase is so small that this behaves like an ideal solution. Reduction of test data by the gas-current method to obtain values of latent heat is accomplished by means of Equation [11].

Interaction Constant A_{aw}

The second virial coefficients A_{aa}, A_{ww} are known temperature functions, values of which are listed in Table 1. According to the prediction of statistical mechanics the interaction constant A_{aw} is also a temperature function, but until recently no experimental data have been available. In discussing these data it is convenient to introduce the ratio

$$\lambda(T) = \frac{2A_{aw}}{A_{aa} + A_{ww}} \quad \ldots\ldots\ldots\ldots\ldots\ldots [12]$$

as a dimensionless interaction constant. Preliminary results from the co-operative investigation referred to previously in-

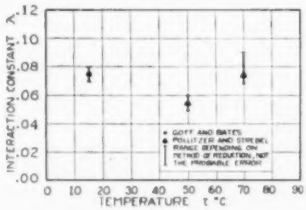

Fig. 2 Variation of λ With Temperature

dicate that, at 15 C, $\lambda = 0.075 \pm 0.005$. These results were obtained by use of a saturation-isotherm method in which a steady stream of dry CO_2-free air is saturated first at high pressure P_1, then dried, then resaturated at low pressure P_2, but at the same temperature as before, then dried again. The two pressures, the common temperature, and the two weights of water collected in the two driers over the same period of time suffice for the determination of the interaction constant λ. Of course, a theory of saturation is also required, but this is easily developed from Equation [8] together with appropriate assumptions regarding the liquid phase.

Evidence of complete saturation, complete drying, and satisfactory performance of the apparatus is obtained by changing the two pressures, by changing the rate of flow, by preliminary saturation at a temperature above or below that of final saturation, and by weighing the dry air. The average deviation of the measured weight of air from that calculated from the measured interaction constant is —0.08 per cent, equivalent to a temperature error of only 0.012 C.

In order to anticipate the probable variation of λ with temperature, certain data, obtained by Pollitzer and Strebel (7), at 50 C and 70 C were reduced. Fig. 2 shows the results and is self-explanatory. These results suggest that, for the purpose of the present paper, a constant value of λ may be taken. The value chosen is $\lambda = 0.075$. Table 1 lists values of the coefficients appearing in Equations [8] and [11]. In this table values of A_{aa}/RT and B_{aa}/RT were computed from the equation of Beattie-Bridgeman (8); values of A_{ww}/RT and of B_{ww}/RT were computed from the equation of Keyes (9); values of B/RT were computed according to Equation [9c], taking $\lambda = 0.075$ as previously explained.

Description of Apparatus

The apparatus is best described with reference to Fig. 3. A detailed description will not be attempted here, but will be in-

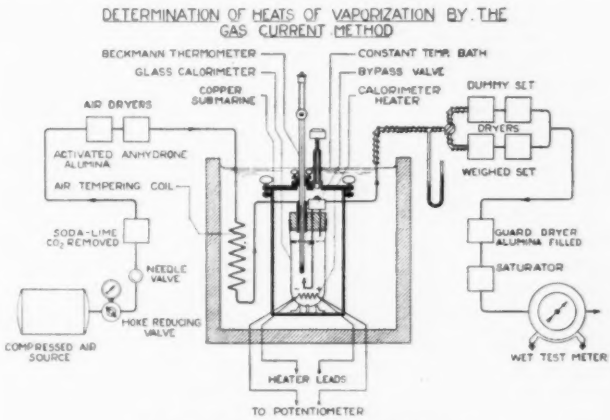

Fig. 3 Experimental Apparatus

cluded in the doctoral dissertation of one of the authors, a copy of which will be kept on file in the Towne Scientific School library.

The source of air is a large tank in which the pressure is maintained at about 63 psi (gage) by automatic control of a laboratory compressor. This pressure is reduced to about 1.5 psi (gage) by means of a Hoke valve, followed by a needle valve for fine regulation. Pressure fluctuations are effectively damped out by passing the air through several large bottles in series. The air is then passed through several large towers filled with soda lime and activated alumina to remove CO_2 and water vapor. Before being admitted to the tempering coil, it passes through a Midvale tower filled with Anhydrone, the drying agent used in the weighed towers following the calorimeter, to insure the same degree of dryness.

The calorimeter proper consists of a single-walled glass vessel 3 in. diam and about 8¾ in. long, closed at the top by a ground-to-fit hard-rubber plug through which extend the air-inlet and outlet tubes, and two additional tubes carrying the heater leads. After being brought to the temperature of the bath by passing through the tempering coil immersed in it, the air enters the inlet tube. In the lower end of this tube is constructed a small jet pump which enables the air to entrap slugs of liquid and carry them upward through the heater and then downward through a long glass spiral intended to prolong intimate contact. The air discharges near the bottom of the calorimeter whence it bubbles upward into the vapor space, entering the outlet tube through an entrainment separator. The upper part of the outlet tube itself is packed with glass wool. The heater is a double-walled glass tube with Nichrome wire wound around the inner tube, the annular space being completely filled with a suitable heat-transfer fluid (Aroclor). The ends of the wire are sealed

through the outer tube into vertical tubes filled to the liquid level with mercury, but extending on upward through the hard-rubber plug. Also extending through the plug is a Beckmann thermometer the bulb of which is immersed in the liquid.

A submarine encloses the calorimeter which rests on four thin bakelite supports to minimize thermal conduction. Several concentric cylinders of aluminum foil are placed between the calorimeter and the submarine wall to minimize convection and radiation. The inner surface of the submarine wall is lined with several layers of this foil with paper backing. Near the top of the submarine is located a four-way valve, by means of which the air stream can be made to by-pass the calorimeter. Copper tubing leads from this valve through the wall of the opposite sides, one connecting to the tempering coil, and one to the glass tube leading to the driers. The remaining two openings into the four-way valve are connected to the air-inlet and outlet tubes of the calorimeter. All connections are made with rubber tubing. The top of the submarine is removable, but is screwed down watertight against a suitable gasket. Projecting through the top are two small hollow copper tubes, each carrying an insulated potential-lead wire inside. These tubes dip into the mercury leads from the heater. At or very near the liquid level in the calorimeter, they are joined with the potential lead wires in order to insure that only the energy supplied to the liquid is measured. In addition, the submarine top carries a device for manipulating the four-way valve from outside, and a watertight sleeve through which the stem of the Beckmann thermometer passes. A water bath surrounds the submarine, support for the latter being designed to insure complete submergence and to minimize heat conduction. Temperature regulation is accomplished in the usual manner by means of a glass thermoregulator filled with alcohol over mercury, a Cenco supersensitive relay, and a suitable resistance heater. A cooling coil is included for operation below room temperature. Temperature regulation to ± 0.001 C was easily maintained.

The glass tubing leading to the driers was wound with Nichrome wire heated from a small current transformer to prevent condensation. After leaving the driers, the air passes through a guard tower filled with saturated alumina, then through a saturator, and finally through a wet-test meter. The driers consist of two Midvale towers in series filled with Anhydrone. In parallel with the main driers is a similar set through which the air is passed before and after the test run.

The heater circuit consists of the heater itself, two small control rheostats in parallel, a standard resistance, and two 6-v storage cells connected in parallel. The standard resistance is a Manganin coil having a resistance of 0.4465 ± 0.0001 international ohms as certified by the National Bureau of Standards. In order to maintain constant voltage, the storage cells are continuously charged during test, as nearly as possible, at the same rate at which they discharge to the heater.

Voltage measurements across the heating coil (including the mercury leads) and across the standard resistance are made with a type K potentiometer, a Weston standard cell, and a suitable galvanometer.

Since only the time rate of supplying electrical energy to the calorimeter is measured it is necessary to determine accurately the time over which the water is collected in the driers. For this purpose a good laboratory stop watch is used, after comparing it with an electric clock over a number of 2-hour periods.

Experimental Procedure

The practice has been adopted of preconditioning the drying towers before each run by blowing them for about 1 hr with the air stream by-passing the calorimeter. The driers are then placed in a desiccator for several hours before being weighed and returned to their place in the apparatus. A prerun of about 1-hr duration is then used for the purpose of obtaining steady-flow conditions, as indicated by stationary readings of the Beckmann thermometer and of the voltage drop across the heater. These conditions are obtained by adjusting the rate of flow and the rate of charging the storage cells. During the prerun, the air by-passes the weighed driers through dummy driers having approximately equal flow resistance. It is generally possible in this manner so to balance the apparatus that the voltage drop across the heater does not vary more than ± 0.00005 v, and the temperature of the liquid does not change, nor differ from that of the bath, by more than ± 0.001 C during test.

The test is started at the instant the sweep hand of the wet-test meter crosses the zero mark. At this instant the air stream is switched to the weighed driers and the stop watch started simultaneously. After approximately 2 hr, the test is ended at the instant the sweep hand of the wet-test meter again crosses the zero mark when the watch is stopped and the air stream switched back to the dummy driers simultaneously. The driers are reweighed, after standing over night in the desiccator. Other precautions are followed in the use of the apparatus, but these need not be described in detail.

The procedure described was not followed exactly in early runs. For instance, some of these were of only 1 hr duration, and the tests were started and stopped by the watch instead of the wet-test meter. Table 2 gives test data covering eight runs with pure water at 30 C.

Reduction of Test Data

Sample calculations for test 29-A will explain the method of reducing the data in Table 2.

(a) $q/RT =$

$$\frac{\underset{\text{int.v}}{0.67400} \times \underset{\text{int.v}}{0.65090} \times \underset{\text{sec}}{7204.0} \times \underset{\text{abs j/int.j}}{1.00019} \times \underset{\text{g/kg}}{1000} \times \underset{\text{kg/k mol}}{18.0154}}{\underset{\text{int.ohm}}{0.4465} \times \underset{\text{mkg/kmol °K}}{847.88} \times \underset{\text{°K}}{303.16} \times \underset{\text{abs j/mkg}}{9.80665} \times \underset{\text{g}}{2.9187}} = 17.336$$

(b) $n_a/n_w = \dfrac{\underset{\text{ft}^3}{3.4600} \times \underset{\text{g/lb}}{453.5924} \times \underset{\text{lb/mol}}{18.0154}}{\underset{\text{ft}^3\text{/lb dry air}}{13.89} \times \underset{\text{g}}{2.9187} \times \underset{\text{lb/mol}}{28.963}} = 24.078;\ x = 0.9601$

(c) $P = \dfrac{78.4}{73.5559} = 1.066$ kg per cm^2; $p_s = 0.043254$ kg per cm^2

(d) $\dfrac{B_{ww}(P - p_s)}{RT} = 0.2811 \times 1.023 = 0.2875$

(e) $\dfrac{xBP}{RT} = 0.9601 \times 0.2623 \times 1.066 = 0.2685$

TABLE 3 REDUCTION OF TEST DATA

TABLE 4 SUMMARY

	q/RT	r/RT	r, (int j/g)
Average of 2-hr runs	17.342 ± 0.0056	17.361 ± 0.0058	2428.7 ± 0.8
Weighted average of all runs	17.341 ± 0.0056	17.360 ± 0.0058	2428.6 ± 0.8
Bureau of Standards	.....	17.367	2429.6

$$(f)\ (1-x)\frac{v'_w}{v}\frac{q}{RT} = \frac{1.00442 \times 17.336}{32{,}929} = 0.0005$$

$$(g)\ \frac{r-q}{RT} = 0.2875 - 0.2685 - 0.0005 = 0.0185$$

$$(h)\ \frac{r}{RT} = 17.336 + 0.0185 = 17.355$$

By way of further explanation; in item (b) the volume of saturated air per pound of dry air at the temperature of the wet-test meter is read directly from Table 6, reference (6), there being no point in extreme accuracy; in item (f) the ratio $v/(1-x)$ is replaced by the specific volume of saturated steam, this being sufficiently accurate.

Table 3 is instructive as showing the relative magnitude of the various terms appearing in Equation [11].

In Table 4, the probable errors are estimated from the following information:

(a) The voltage readings are limited by the sensitivity of the galvanometer to 1 part in 20,000.

(b) There may be a residual error in the time measurements of about 1 part in 7200.

(c) The weighings are probably accurate to 1 part in 5600.

(d) The probable error in the resistance of the standard coil is 1 part in 4000.

(e) The value of λ is uncertain by about 1 part in 15.

The method of weighting individual runs is to weight each in proportion to its duration.

Conclusions

The following conclusions are drawn:

1 The present apparatus is capable of an high degree of consistency and reproductibility.

2 Direct measurements by the gas-current method require reduction to account for the effect of intermolecular forces in the vapor phase.

3 This reduction is now possible since data on the interaction constant for moist air have recently been made available.

4 After reduction, the data on the latent heat of pure water at 30 C are in satisfactory accord with recent values from the National Bureau of Standards.

5 Higher precision not only in the data of the gas-current method itself but also in the knowledge of latent heat from independent sources would be required to make the method suitable for the measurement of the interaction constant.

Note on Plane Strain

By W. R. OSGOOD,[1] WASHINGTON, D. C.

THE strain in an elastic body is called plane strain if it permits choosing a rectangular co-ordinate system in the body, such that the displacements normal to one of the co-ordinate axes are independent of the value of that co-ordinate, and the component of linear strain parallel to that axis is constant.

In general, except in the case of bodies of cylindrical (in its general sense, including prismatic) shape and of homogeneous and isotropic material, the distribution of surface and body forces necessary to set up a state of plane strain is very complicated. For this reason discussions of plane strain are usually limited to strains in bodies of cylindrical shape, and it is common to characterize plane strain by some such statement as, "if a long, cylindrical or prismatic, elastic body of uniform and isotropic material is loaded by forces which are perpendicular to the longitudinal elements and which do not vary along the length of the body, then, except possibly in the immediate neighborhood of the ends, the body will remain cylindrical, and plane cross sections will remain plane." This, however, is not an adequate characterization. A long rectangular plate loaded along the long edges by equal and opposite uniformly distributed couples with axes parallel to the long dimension, is a simple example in which these conditions of loading are met, and yet the body does not remain cylindrical at a distance from the ends. Consequently, the strain is not plane strain.

It is well known that under the action of such couples the surface of the plate becomes an anticlastic surface with uniform principal curvatures[2]—it is nowhere cylindrical. If the problem is analyzed as a problem in plane strain, the analysis will show that the boundary conditions require, in addition, forces along the short edges to maintain a cylindrical shape for the deformed plate. The stresses on cross sections parallel to the long edges are unaffected by the forces acting on the short edges. It is easy to see in this example what is going on, but now let us consider another case of loading.

Suppose that the long rectangular plate is held fixed along one long edge and loaded like a cantilever beam by a uniformly distributed force along the opposite edge. If the problem is analyzed as a problem in plane strain, one finds the shearing stress τ_{xy} given by

$$\tau_{xy} = \frac{P}{2I}(b^2 - y^2)$$

where the origin of co-ordinates is taken at the free long edge, at the mid-plane; the axis of x is taken in the mid-plane, at right angles to and positive toward the fixed edge; the axis of y is taken normal to the mid-plane; P is the total load on the free long edge; I is the least moment of inertia of a cross section parallel to a long edge; and b is one half the thickness of the plate. Here again, the problem considered as one in plane strain will require forces to be acting along the short edges. Unless they do, the plate is nowhere cylindrical, and[3]

$$\tau_{xy} = \frac{1}{1+\nu}\frac{P}{2I}(b^2 - y^2)$$

where ν is Poisson's ratio. In this case the forces required at the ends (short edges) by the plane-strain solution alter the picture radically, and their effects are felt at any distance from the ends (short edges). Evidently the statement in the second paragraph of this note is not sufficient to characterize a state of plane strain. The applied forces there mentioned must not only be perpendicular to the longitudinal elements and must not vary along the length of the body, but in addition, they must give rise to displacements such that the body remains cylindrical. With the axis of z taken along the centroidal axis of the body (cylinder), the applied forces will give rise to the required displacements if they result in normal components of stress σ_x and σ_y such that

$$\int\int_A (\sigma_x + \sigma_y)\, x dA = \int\int_A (\sigma_x + \sigma_y)\, y dA = 0$$

where A is the cross-sectional area of the body. This condition merely states that the body is not bent about any transverse axis.

Determining Critical States of Equilibrium of Plates and Shells Under Initial Stress

By H. HENCKY,[1] MAINZ, GERMANY

The purpose of this paper is to show that Rayleigh's energy method, used by Timoshenko for the determination of critical loads in plates and shells, is capable of an important generalization.[2] The work involved is a direct continuation of the energy method of Timoshenko and is based on the principle of virtual work. According to this principle the variation of the work of the outer forces together with the variation of the kinetic energy is equal to the variation of the elastic energy stored up in the body. The author develops a series of formulas, by means of which the stability of a cylindrical shell under various conditions of stress may be determined. The practical applications of these formulas, requiring only a fundamental knowledge of the mathematics of engineering, are illustrated by suitable examples.

IF a virtual displacement is applied to a stressed body, a certain amount of elastic energy is stored up and at the same time the stresses, acting in the body and on the boundary, perform work during this virtual displacement. When the elastic energy is just equal to this work, we have the case of indifferent equilibrium; when it is greater, equilibrium is not possible, and the body vibrates about a middle position. If the elastic energy is smaller, the disturbing forces will prevail and the body is in a state of unstable equilibrium.

Though much has been written concerning this problem, it must be concluded that there is no simple method of analysis of unstable equilibrium in curved plates and shells. Therefore, this paper is being devoted to the explanation of a method which can be readily applied. Although some mathematical analysis is necessary to deduce this method, its practical application does not require a more extensive knowledge of mathematics than that with which an able student of engineering is familiar.

This work is a direct continuation of the work of Timoshenko, who applied the energy method in solving numerous practical problems in stability. However, in applying his method to problems of curved shells, we become aware that there are some things to be desired: (1) The question arises: What are the conditions at the free but stressed boundaries? (2) Since there can exist an arbitrary system of initial stresses varying from point to point, how can we determine the question of stability? To answer these questions we begin with the most general principle of mechanics, i.e., the principle of virtual work.

The Generalized Principle of Virtual Work

According to the principle of virtual work, the variation of the work of the outer forces together with the variation of the kinetic energy is equal to the variation of the elastic energy stored up in the body. In order to apply this principle to our problem, we consider the following three states of the body:

State 1 is the state of rest under the boundary stresses P_x, P_y, P_z, the inner stresses σ_x, σ_y, σ_z, T_x, T_y, T_z, and the body forces X, Y, Z.

State 2 is not necessarily a state of rest. In state 1 we apply the displacements Δu, Δv, Δw leading to state 2 and accompanied by the stresses $\sigma_x + \Delta\sigma_x$, ... $T_x + \Delta T_x$, ... and boundary stresses $P_x + \Delta P_x$, ... The displacements Δu, ... are so small that the second powers of the strains are to be neglected as compared with the first, but they are not infinitely small.

State 3 is the state of the body when we apply, moreover, infinitely small displacements $\delta\Delta u$, $\delta\Delta v$, $\delta\Delta w$.

Now we must bear in mind that all the quantities entering in the equation of virtual work are functions of a system of coordinates fixed in the body in state 1 but the equation of virtual work must be written for state 2. The general problem would be a very complicated one[3] but, since we are dealing only with bodies having at least one quite small dimension such as bars and thin shells, we know that the strains are much smaller than the rotations of the elements of the body. We may therefore neglect the strains entirely as compared with the rotations provided we are dealing with sufficiently thin shells.

It is known from the theory of elasticity that if Δu, Δv, Δw are the displacements of particles of a deformed body the rotations are given by three equations of the type

$$\Delta\omega_x = \frac{1}{2}\left(\frac{\partial\Delta w}{\partial y} - \frac{\partial\Delta v}{\partial z}\right) \quad \ldots\ldots\ldots\ldots [1]$$

and strains by

$$\left.\begin{aligned} \Delta e_x &= \frac{\partial\Delta u}{\partial x} \quad \ldots\ldots\ldots\ldots \\ \Delta\gamma_x &= \frac{1}{2}\left(\frac{\partial\Delta w}{\partial y} + \frac{\partial\Delta v}{\partial z}\right) \quad \ldots\ldots\ldots\ldots \end{aligned}\right\} \quad \ldots\ldots [2]$$

The equation of virtual work written for state 1 is

$$\begin{aligned} &\int\int dO(P_x\delta\Delta u + P_y\delta\Delta v + P_z\delta\Delta w) \\ &= \int\int\int dV\left(\sigma_x\frac{\partial\delta\Delta u}{\partial x} + T_z\frac{\partial\delta\Delta u}{\partial y} + T_y\frac{\partial\delta\Delta u}{\partial z} + T_z\frac{\partial\delta\Delta v}{\partial x}\right. \\ &\left. + \sigma_y\frac{\partial\delta\Delta v}{\partial y} + T_x\frac{\partial\delta\Delta v}{\partial z} + T_y\frac{\partial\delta\Delta w}{\partial x} + T_z\frac{\partial\delta\Delta w}{\partial y} + \sigma_z\frac{\partial\delta\Delta w}{\partial z}\right) \\ &\quad - \int\int\int dV(X\delta\Delta u + Y\delta\Delta v + Z\delta\Delta w) \quad \ldots\ldots [3] \end{aligned}$$

Integrating by parts we find

$$\int\int dO\left[\{P_x - \sigma_x\cos(nx) - T_z\cos(ny) - T_y\cos(nz)\}\delta\Delta u\right.$$

$$+ \{P_y - T_z \cos(nx) - \sigma_y \cos(ny) - T_x \cos(nz)\}\delta\Delta v$$
$$+ \{P_z - T_y \cos(nx) - T_x \cos(ny) - \sigma_z \cos(nz)\}\delta\Delta w]$$
$$+ \int\int\int dV \left\{\left(\frac{\partial\sigma_x}{\partial x} + \frac{\partial T_z}{\partial y} + \frac{\partial T_y}{\partial z} + X\right)\delta\Delta u\right.$$
$$+ \left(\frac{\partial T_z}{\partial x} + \frac{\partial\sigma_y}{\partial y} + \frac{\partial T_y}{\partial z} + Y\right)\delta\Delta v$$
$$\left. + \left(\frac{\partial T_y}{\partial x} + \frac{\partial T_x}{\partial y} + \frac{\partial\sigma_z}{\partial z} + Z\right)\delta\Delta w\right\} = 0$$

Since the displacements $\delta\Delta u \ldots$ are perfectly arbitrary, we conclude that the coefficients of these quantities must vanish, but it is not our aim now to obtain the differential equations of the problem. We wish rather to retain the integral form, and we shall see presently that in so doing we reach a new and practically important statement.

Though the foregoing integral could be written for state 1, we will now introduce the small displacements $\Delta u, \ldots$ leading from state 1 to state 2, and then write the equation of virtual work for state 2. During these displacements, the stresses $\sigma_x, \ldots, T_x, \ldots$ acting on an element of the body change to $\sigma_x + \Delta\sigma_x, \ldots, T_x + \Delta T_x, \ldots$, while the element of the body is rotated through the angles $\Delta\omega_x, \ldots$. The strains which accompany these displacements $\Delta u, \ldots$ are neglected for the reasons mentioned.

Referring the rotated element of the body with stresses $\sigma_x + \Delta\sigma_x, \ldots, T_x + \Delta T_x, \ldots$, acting on it to coordinate axes fixed in the body in state 1, we obtain the nine components of stress

$$X_x = \sigma_x + \Delta\sigma_x + T_y\Delta\omega_y - T_z\Delta\omega_z$$
$$Y_x = T_z + \Delta T_z + \sigma_x\Delta\omega_z - T_y\Delta\omega_x$$
$$Z_x = T_y + \Delta T_y + T_z\Delta\omega_x - \sigma_x\Delta\omega_y$$

with similar expressions for $X_y, \ldots, X_z, \ldots$.

Similarly the three boundary stresses in the direction of the x, y, and z axes are of the type

$$P_x + \Delta P_x + P_z\Delta\omega_y - P_y\Delta\omega_z, \text{ etc.}$$

It is to be noted that $\Delta P_x, \ldots$ are increments of boundary force per unit area which causes the body to pass from state 1 into state 2. If a body is in a state of indifferent equilibrium, no increments $\Delta P_x, \ldots$ are required to cause collapse. Thus the condition that a body is in the state of indifferent equilibrium is that $\Delta P_x = 0;\ \Delta P_y = 0;\ \Delta P_z = 0$.

If we write the equation of virtual work for state 2 for the general case that state 2 is not a state of equilibrium, then subtract from it Equation [3], and put ΔP_x, ΔP_y, ΔP_z equal to zero, we find

$$\int\int dO\{(P_z\Delta\omega_y - P_y\Delta\omega_z)\delta\Delta u + (P_x\Delta\omega_z - P_z\Delta\omega_x)\delta\Delta v$$
$$+ (P_y\Delta\omega_x - P_x\Delta\omega_y)\delta\Delta w\} + \int\int\int dV\,\frac{\mu}{2}\,\delta\left\{\left(\frac{\partial\Delta u}{\partial t}\right)^2\right.$$
$$\left. + \left(\frac{\partial\Delta v}{\partial t}\right)^2 + \left(\frac{\partial\Delta w}{\partial t}\right)^2\right\} = \int\int\int dV\left\{\Delta\sigma_x\frac{\partial\delta\Delta u}{\partial x}\right.$$
$$+ \Delta\sigma_y\frac{\partial\delta\Delta v}{\partial y} + \Delta\sigma_z\frac{\partial\delta\Delta w}{\partial z} + \Delta T_x\left(\frac{\partial\delta\Delta w}{\partial y} + \frac{\partial\delta\Delta v}{\partial z}\right)$$
$$+ \Delta T_y\left(\frac{\partial\delta\Delta u}{\partial z} + \frac{\partial\delta\Delta w}{\partial x}\right) + \Delta T_z\left(\frac{\partial\delta\Delta v}{\partial x} + \frac{\partial\delta\Delta u}{\partial y}\right)\Big\}$$
$$+ \int\int\int dV\left\{(T_y\Delta\omega_y - T_z\Delta\omega_z)\frac{\partial\delta\Delta u}{\partial x}\right.$$
$$+ (T_x\Delta\omega_y - \sigma_y\Delta\omega_z)\frac{\partial\delta\Delta u}{\partial y} + (\sigma_z\Delta\omega_y - T_x\Delta\omega_z)\frac{\partial\delta\Delta u}{\partial z}$$
$$+ (\sigma_x\Delta\omega_z - T_y\Delta\omega_x)\frac{\partial\delta\Delta v}{\partial x} + (T_z\Delta\omega_z - T_x\Delta\omega_x)\frac{\partial\delta\Delta v}{\partial y}$$
$$+ (T_y\Delta\omega_z - \sigma_z\Delta\omega_x)\frac{\partial\delta\Delta v}{\partial z} + (T_z\Delta\omega_z - \sigma_z\Delta\omega_y)\frac{\partial\delta\Delta w}{\partial x}$$
$$\left. + (\sigma_y\Delta\omega_x - T_z\Delta\omega_y)\frac{\partial\delta\Delta w}{\partial y} + (T_x\Delta\omega_x - T_y\Delta\omega_y)\frac{\partial\delta\Delta w}{\partial z}\right\}$$

Introducing here the relations

$$\delta\Delta\omega_x + \delta\Delta\gamma_x = \frac{\partial\delta\Delta w}{\partial y}, \quad \delta\Delta\omega_y + \delta\Delta\gamma_y = \frac{\partial\delta\Delta u}{\partial z},$$
$$\delta\Delta\omega_z + \delta\Delta\gamma_z = \frac{\partial\delta\Delta v}{\partial x}$$
$$\delta\Delta\gamma_x - \delta\Delta\omega_x = \frac{\partial\delta\Delta v}{\partial z}, \quad \delta\Delta\gamma_y - \delta\Delta\omega_y = \frac{\partial\delta\Delta w}{\partial x},$$
$$\delta\Delta\gamma_z - \delta\Delta\omega_z = \frac{\partial\delta\Delta u}{\partial y}$$

and neglecting the components of strain, $\Delta e_x, \ldots, \Delta\gamma_x, \ldots$ as compared with the rotations, we find

$$\int\int dO\{(P_z\Delta\omega_y - P_y\Delta\omega_z)\delta\Delta u + (P_x\Delta\omega_z - P_z\Delta\omega_x)\delta\Delta v$$
$$+ (P_y\Delta\omega_x - P_x\Delta\omega_y)\delta\Delta w\} + \delta\Delta T + \int\int\int dV\{-(\sigma_y$$
$$+ \sigma_z)\Delta\omega_x + T_z\Delta\omega_y + T_y\Delta\omega_z\}\,\delta\Delta\omega_x + \{T_z\Delta\omega_x - (\sigma_z$$
$$+ \sigma_x)\Delta\omega_y + T_x\Delta\omega_z\}\,\delta\Delta\omega_y + \{T_y\Delta\omega_x + T_x\Delta\omega_y - (\sigma_x$$
$$+ \sigma_y)\Delta\omega_z\}\,\delta\Delta\omega_z = \delta\Delta A$$

where δT is the variation of the kinetic energy and δA is the variation of the elastic energy.

We are now able to draw our final conclusion by specializing the virtual displacement. We assume that $\delta\Delta u$ is the differential of Δu and that $\Delta u, \ldots$ are so small that the higher powers of $\Delta\omega_x, \ldots$ may be neglected. Under these circumstances, we can integrate the preceding equation, introducing the factor $^1/_2$ because $\Delta u, \ldots$ increase from zero to their final values.

Thus the final equation of virtual work will be

$$\frac{1}{2}\int\int dO\{(P_z\Delta\omega_y - P_y\Delta\omega_z)\Delta u + (P_x\Delta\omega_z - P_z\Delta\omega_x)\Delta v$$
$$+ (P_y\Delta\omega_x - P_x\Delta\omega_y)\Delta w\} + \Delta T + \frac{1}{2}\int\int\int dV$$
$$\{-\sigma_x(\Delta\omega_y^2 + \Delta\omega_z^2) - \sigma_y(\Delta\omega_x^2 + \Delta\omega_z^2) - \sigma_z(\Delta\omega_x^2 + \Delta\omega_y^2)$$
$$+ 2T_x\Delta\omega_y\Delta\omega_z + 2T_y\Delta\omega_x\Delta\omega_z + 2T_z\Delta\omega_x\Delta\omega_y\} = \Delta A \quad \ldots [4a]$$

where

$$\Delta T = \int\int\int \frac{\mu}{2}\left\{\left(\frac{\partial\Delta u}{\partial t}\right)^2 + \left(\frac{\partial\Delta v}{\partial t}\right)^2 + \left(\frac{\partial\Delta w}{\partial t}\right)^2\right\} dV \quad \ldots [4b]$$

and

$$\delta\Delta A = \int\int\int dV\{\Delta\sigma_x\delta\Delta e_x + \Delta\sigma_y\delta\Delta e_y + \Delta\sigma_z\delta\Delta e_z$$
$$+ 2\Delta T_x\delta\Delta\gamma_x + 2\Delta T_y\delta\Delta\gamma_y + 2\Delta T_z\delta\Delta\gamma_z\} \quad \ldots [4c]$$

The relation between the stresses $\Delta\sigma_x, \ldots, \Delta T_x, \ldots$ and the boundary stresses $\Delta P_x, \ldots$ is the same as for the stresses in state 1, that is

$$\Delta P_x = \Delta\sigma_x \cos(nx) + \Delta T_z \cos(ny) + \Delta T_y \cos(nz) \ldots [4d]$$

with similar expressions for ΔP_y and ΔP_z.

We conclude from these equations that the only term in which the strains have to be considered is the term ΔA. We assume the usual linear relationship between stress and strain components.

Taking the x direction as the direction of the normal to the plate or shell, we now introduce a device by which we can avoid the complicated theory of curved shells. If we let the displacements of the middle surface of the shell be given by Δu_0, Δv_0, Δw_0, then we can express the displacements of a point not on the middle surface by Δu_0, ... and linear functions of the distance of the point from the middle surface. Thus, we have a plate or shell subjected to plane stress. The stresses $\Delta\sigma_x$, ΔT_y, ΔT_z are statically determined and the stresses $\Delta\sigma_y$, $\Delta\sigma_z$, ΔT_x are connected with the strains Δe_y, Δe_z, $\Delta\gamma_x$ by a linear law. For an isotropic body, this law can be written[4]

$$\left.\begin{aligned} \Delta\sigma_y &= 2G\left\{\Delta e_y + \frac{1}{m-1}(\Delta e_y + \Delta e_z)\right\} \\ \Delta\sigma_z &= 2G\left\{\Delta e_z + \frac{1}{m-1}(\Delta e_y + \Delta e_z)\right\} \\ \Delta T_x &= 2G\,\Delta\gamma_x \end{aligned}\right\} \ldots\ldots [5a]$$

where m is the reciprocal of Poisson's ratio. The strains Δe_x, $\Delta\gamma_y$, $\Delta\gamma_z$ disappear as a consequence of our assumptions concerning the displacements Δu, ... With the aid of Equations [5a] we can integrate Equation [4c] with δ as a differential and we find

$$\Delta A = G\left\{\Delta e_y^2 + \Delta e_z^2 + 2\Delta\gamma_x^2 + \frac{1}{m-1}(\Delta e_y^2 + \Delta e_z^2 + 2\Delta e_y \Delta e_z)\right\} \ldots [5b]$$

Having Equations [4a], [4b], and [5b], the solution of our problem is completed. To illustrate the practical application of our equations, we shall now consider some simple examples.

Stability of a Cylindrical Shell Under Various Conditions

There are, of course, many ways in which a shell can collapse, but in most cases the form of the virtual displacement leading to destruction is known. Our method determines whether the assumed displacement of the middle surface causes the body to become unstable.

We take the x co-ordinate in the radial direction, the y co-ordinate in the direction of the tangent and the z co-ordinate in the direction of the axis of the cylindrical shell. To remove the dimensional quantities from the differentials we put

$$r = a\rho; \quad z = l\zeta$$

Taking the displacements of the middle surface as Δu_0, Δv_0, Δw_0, we obtain for the displacement of an arbitrary point, which is assumed to remain on the normal to the middle surface, the following equations

$$\left.\begin{aligned} \Delta u &= \Delta u_0 \\ \Delta v &= \rho\,\Delta v_0 - (\rho-1)\frac{\partial \Delta u_0}{\partial\phi} \\ \Delta w &= \Delta w_0 - \frac{a}{l}(\rho-1)\frac{\partial \Delta u_0}{\partial\zeta} \end{aligned}\right\} \ldots\ldots [6]$$

The rotations are given by the following equations in the cylindrical system of co-ordinates

$$\left.\begin{aligned} 2\Delta w_r &= \frac{1}{r}\frac{\partial \Delta w}{\partial\phi} - \frac{\partial \Delta v}{\partial z} \\ 2\Delta\omega_\phi &= \frac{\partial \Delta u}{\partial z} - \frac{\partial \Delta w}{\partial r} \\ 2\Delta\omega_z &= \frac{1}{r}\frac{\partial(r\Delta v)}{\partial r} - \frac{1}{r}\frac{\partial \Delta u}{\partial\phi} \end{aligned}\right\} \ldots\ldots [7a]$$

and the strains become

$$\left.\begin{aligned} \Delta e_\phi &= \frac{1}{r}\frac{\partial \Delta v}{\partial\phi} + \frac{\Delta u}{r} \\ \Delta e_z &= \frac{\partial \Delta w}{\partial z} \\ 2\Delta\gamma_r &= \frac{1}{r}\frac{\partial \Delta w}{\partial\phi} + \frac{\partial \Delta v}{\partial z} \end{aligned}\right\} \ldots\ldots [7b]$$

Substituting Equation [6] into Equations [7a] and [7b] we find

$$\left.\begin{aligned} \Delta\omega_r &= -\frac{1}{2l}\frac{\partial \Delta v_0}{\partial\zeta} + \frac{1}{2a}\frac{\partial \Delta w_0}{\partial\phi} \\ \Delta\omega_\phi &= \frac{1}{l}\frac{\partial \Delta u_0}{\partial\zeta} \\ \Delta\omega_z &= \frac{1}{a}\left(\Delta v_0 - \frac{\partial \Delta u_0}{\partial\phi}\right) \end{aligned}\right\} \ldots\ldots [8a]$$

$$\left.\begin{aligned} \Delta e_\phi &= \frac{1}{a}\left\{\frac{\partial \Delta v_0}{\partial\phi} + \frac{\Delta u_0}{\rho} - \left(1-\frac{1}{\rho}\right)\frac{\partial^2 \Delta u_0}{\partial\phi^2}\right\} \\ \Delta e_z &= \frac{1}{l}\frac{\partial \Delta w_0}{\partial\zeta} - (\rho-1)\frac{a}{l^2}\frac{\partial^2 \Delta u_0}{\partial\zeta^2} \\ 2\Delta\gamma &= \frac{1}{a\rho}\frac{\partial \Delta w_0}{\partial\phi} + \frac{1}{l}\left\{\rho\frac{\partial \Delta v_0}{\partial\zeta} - \left(\rho-\frac{1}{\rho}\right)\frac{\partial^2 \Delta u_0}{\partial\phi\,\partial\zeta}\right\} \end{aligned}\right\} \ldots\ldots [8b]$$

Using Equation [5a], we obtain the stresses

$$\left.\begin{aligned} \Delta\sigma_\phi &= 2G\frac{m}{m-1}\left\{\frac{\partial \Delta v_0}{\partial\phi} + \frac{\Delta u_0}{\rho} - \left(1-\frac{1}{\rho}\right)\frac{\partial^2 \Delta u_0}{\partial\phi^2}\right\} \\ &\quad + \frac{2G}{l(m-1)}\left\{\frac{\partial \Delta w_0}{\partial\zeta} - \frac{a}{l}(\rho-1)\frac{\partial^2 \Delta u_0}{\partial\zeta^2}\right\} \\ \Delta\sigma_z &= 2G\frac{m}{m-1}\frac{1}{l}\left\{\frac{\partial \Delta w_0}{\partial\zeta} - (\rho-1)\frac{a}{l}\frac{\partial^2 \Delta u_0}{\partial\zeta^2}\right\} \\ &\quad + \frac{2G}{m-1}\frac{1}{a}\left\{\frac{\partial \Delta v_0}{\partial\phi} + \frac{\Delta u_0}{\rho} - \left(1-\frac{1}{\rho}\right)\frac{\partial^2 \Delta u_0}{\partial\phi^2}\right\} \\ \Delta T &= \frac{G}{a}\left\{\frac{1}{\rho}\frac{\partial \Delta w_0}{\partial\phi} + \frac{a}{l}\rho\frac{\partial \Delta v_0}{\partial\zeta} - \frac{a}{l}\left(\rho-\frac{1}{\rho}\right)\frac{\partial^2 \Delta v_0}{\partial\phi\,\partial\zeta}\right\} \end{aligned}\right\} \ldots [9]$$

We shall now investigate the displacements of the middle surface taken in the form

$$\left.\begin{aligned} \Delta u_0 &= 2Bf(\zeta)\cos 2\phi \\ \Delta v_0 &= -Bf(\zeta)\sin 2\phi \\ \Delta w_0 &= 0 \end{aligned}\right\} \ldots\ldots [10]$$

where B is a perfectly arbitrary amplitude and f is an arbitrary function. Using Equations [8a] and [8b] we find

$$\left.\begin{aligned} \Delta\omega_r &= \frac{B}{2l}f'\sin 2\phi \\ \Delta\omega_\phi &= \frac{2B}{l}f'\cos 2\phi \\ \Delta\omega_z &= \frac{3B}{a}f\sin 2\phi \end{aligned}\right\} \ldots\ldots [11a]$$

[4] A. E. H. Love, ref. (2), pp. 207–208.

$$\left.\begin{aligned} \Delta e_\phi &= 6\frac{Bf}{a}\left(1-\frac{1}{\rho}\right)\cos 2\phi \\ \Delta e_z &= -\frac{2aBf''}{l^2}(\rho-1)\cos 2\phi \\ \Delta\gamma &= \frac{B}{2l}f'\left(3\rho-\frac{4}{\rho}\right)\sin 2\phi \end{aligned}\right\} \quad \ldots\ldots\ldots [11b]$$

1 For a free cylinder under outer pressure, $f = 1$ and Equations [11a] and [11b] become

$$\Delta\omega_r = 0;\quad \Delta\omega_\phi = 0;\quad \Delta\omega_z = \frac{3B}{a}\sin 2\phi$$

$$\Delta e_\phi = 6\frac{B}{a}\left(1-\frac{1}{\rho}\right)\cos 2\phi;\quad \Delta e_z = 0;\quad \Delta\gamma = 0$$

also

$$\int\int dO\,\Delta\omega_z\,\Delta v_0 = -3\pi l B^2$$

$$\int\int\int dV\,\Delta\omega_z{}^2 = 9\pi l B^2\left(\frac{h}{a}\right)$$

$$\int\int\int dV\,\Delta e_\phi{}^2 = 3\pi l B^2\left(\frac{h}{a}\right)^3$$

Substituting into Equation [4a] we have

$$\frac{p}{2}\pi B^2 l(3+9) = G\pi l B^2\left(\frac{h}{a}\right)^3\left(3+\frac{3}{m-1}\right)$$

from which we find the well-known equation

$$p_{\text{critical}} = \frac{3D}{a^3}$$

where D is the flexural rigidity of the shell.

2 For the case of the cylindrical vessel with rigid covers under uniform external pressure, we take

$$\begin{aligned} f(\zeta) &= 1+\cos\pi\zeta \\ f'(\zeta) &= -\pi\sin\pi\zeta \\ f''(\zeta) &= -\pi^2\cos\pi\zeta \end{aligned}$$

At the boundaries

$$\zeta = \pm 1$$

so that f and f' will disappear. From Equations [11a] and [11b] we find

$$\begin{aligned} \Delta\omega_r &= \frac{f'}{2l}B\sin 2\phi \\ \Delta\omega_\phi &= \frac{2B}{l}f'\cos 2\phi \\ \Delta\omega_z &= \frac{3B}{a}f\sin 2\phi \\ \Delta e_\phi &= \frac{6B}{a}f\left(1-\frac{1}{\rho}\right)\cos 2\phi \\ \Delta e_z &= -\frac{2aB}{l^2}f''(\rho-1)\cos 2\phi \\ \Delta\gamma &= \frac{B}{2l}f'\left(3\rho-\frac{4}{\rho}\right)\sin 2\phi \end{aligned}$$

The initial stresses are

$$\sigma_r \cong 0$$

$$\sigma_\phi = -p\frac{a}{h}$$

$$\sigma_z = -\frac{p}{2}\frac{a}{h}$$

Using Equations [4a] and [5b] and taking $m = 4$ we find

$$\frac{p_{(\text{crit})}}{2G} = \frac{\frac{h}{a}\frac{\pi^2}{4}\left(\frac{a}{l}\right)^2+\left(\frac{h}{a}\right)^3\left\{6+\frac{59}{48}\pi^2\left(\frac{a}{l}\right)^2+\frac{2}{9}\pi^4\left(\frac{a}{l}\right)^4\right\}}{18+\frac{19}{16}\pi^2\left(\frac{a}{l}\right)^2}$$

The critical load will always have the form

$$\frac{p_{(\text{crit})}}{2G} = A_{\text{extensional}}\left(\frac{h}{a}\right)+A_{\text{bending}}\left(\frac{h}{a}\right)^3$$

Since arbitrarily we have assumed the virtual displacements for our problem, it will be useful in studying the validity of our result to examine the last equation in some detail. The critical load is seen to be the sum of two terms which are related to an energy. The first term is the result of potential energy of strain of the middle surface, while the second term gives the influence of the energy of bending. When the first term gives such values of the critical load that the corresponding stress reaches the yield point, we must conclude that the assumed virtual displacement is not the correct one. It has been proved that a closed shell cannot undergo a deformation in which the extensional strains disappear. That means the term linear in h/a is always present and we must choose our virtual displacements in order to make the value of A_{ext} very small.

When the problem admits a solution in trigonometrical series, it is easy to do so. Putting, for instance

$$\Delta u_0 = 2B\{1+\cos(2m+1)\pi\zeta\}\cos n\phi$$

$$\Delta v_0 = -B\{1+\cos(2m+1)\pi\zeta\}\sin n\phi$$

$$\Delta w_0 = 0$$

we have a solution satisfying the same boundary conditions previously considered and having two parameters m and n which can be so chosen that the extensional energy is as small as possible. Timoshenko and Westergaard have shown[5] how in this way not only approximations but exact solutions can be obtained.

We wish to emphasize that it is not necessary to consider the three stress couples and the three stress resultants dealt with in the classical theory of elasticity. The stresses needed are given by Equations [9]. In the present method, we consider as unknowns only the displacements of the middle surface, and determine the displacements of points of the shell not on the middle surface from the assumption that the normals remain normals and that the distance from the middle surface does not change.

Although the general Equations [4a] and [5b] are written in Cartesian co-ordinates, only the components of vectors and tensors occur so that the transition to any curvilinear system of co-ordinates is not difficult.

The Mechanism of Cavitation Erosion

By T. C. POULTER,[1] CHICAGO, ILL.

After pointing out the interrelation between corrosion resistance, caustic embrittlement, fatigue, creep, and other phenomena of metals, the author cites the results of experiments on glass and quartz rods, subjected to high liquid pressures, as indicative of the action which probably occurs in cavitation erosion. To demonstrate the mechanism of cavitation on this basis, an investigation was conducted, in which tests were made on gray-cast-iron specimens in water, alcohol, glycerin, and paraffin oil, using a magnetostriction oscillator as the source of energy. The results of the tests which are reported bear out the theory. Materials and protective coatings which reduce cavitation erosion greatly, and the effect of the presence of hydrogen in the liquid are discussed.

CORROSION resistance, caustic embrittlement, steam erosion, cavitation erosion, gun-barrel erosion, wire drawing, fatigue, penetration of gases into metals, penetration of liquids into metals, and creep of metals are phenomena which are so completely interrelated that it is impossible to arrive at a proper explanation of one without at the same time shedding considerable light upon the others. The differences between the various phenomena referred to likely fall into two classes: (1) Difference in the ratio of the chemical to the physical nature of the phenomena; and (2) the order in which these take place. The fact that in some cases the fatigue resistance of a metal can be varied as much as tenfold by surrounding the test sample with a different gas indicates that fatigue is not entirely a physical phenomenon. Cavitation erosion has been considered somewhat of an isolated phenomenon, but a study of it has led to interesting information which may throw light upon other of these effects.

Investigation of Properties of Glass and Fused Quartz Under Liquid Pressure

In the course of certain investigations, being conducted in the field of extreme-pressure research, it became necessary to study the properties of glass and fused quartz when surrounded by liquids at high pressures. Differences in the behavior of various liquids on pressure windows had suggested that in some cases liquids were penetrating the glass or quartz of the windows.[2] It was found that pressure windows would withstand several times as much pressure if oil or glycerin were used to transmit the pressure, than they would if water, ether, or alcohol were employed. Windows surrounded by water, ether, or alcohol would frequently break on lowering the pressure, even though they had previously withstood much greater pressures.

A series of tests was undertaken in which pieces of glass or fused-quartz rod, 3 to 4 mm in diam and about 15 mm long, were placed in a piece of rubber tubing 5 cm long, and 6 mm ID. This tube was filled with the desired liquid and stoppered at both ends. It was then placed in a pressure cylinder, surrounded by oil, and the pressure applied.

If the pressure were built up to 15,000 atm or higher and immediately released, the glass or quartz rod would not be affected, even though surrounded by any one of the five liquids in question. In all cases, 30 sec were required to reach the maximum pressure and about 5 sec to reduce it to zero. It was found that if instead of dropping the pressure immediately, it is maintained for 5 min and then rapidly dropped to zero, the glass or quartz rods which are surrounded by alcohol, ether, or water will be broken up into short plates, whereas, those rods surrounded by paraffin, oil, or glycerin are unaffected. Now, if the pressure is maintained for 20 min instead of 5 min, and then rapidly dropped to zero, instead of forming smooth plates, the rod is shattered in all directions forming small irregular pieces. If the pressure is built up as before but allowed to go down very slowly (over a period of several hours), the specimens will not be affected regardless of the liquid surrounding them. The results of these experiments are shown in Fig. 1, in which the actual specimens were laid out on a chart and photographed.

Several glass and quartz disks were then cut from flat stock 4 mm thick. One of these disks was placed in the middle of the

[2] "Permeability of Glass and Fused Quartz to Ether, Alcohol, and Water at High Pressure," by T. C. Poulter and R. O. Wilson, *Physical Review*, vol. 40, no. 5, June 1, 1932, pp. 877–880.

Contributed by the Applied Mechanics Division, and presented at the Annual Meeting, New York, N. Y., December 1–5, 1941, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until April 10, 1942, for publication at a later date. Discussion received after the closing date will be returned.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors and not those of the Society.

rubber tube so that different liquids could be used on opposite sides of the glass. The results with these disks were similar to those with the glass rod, i.e., the side of a disk in contact with water, ether, or alcohol is shattered, unless the pressure is dropped immediately or allowed to subside very slowly; whereas, the side in contact with paraffin, oil, or glycerin remains intact in all cases. This fracturing cannot be explained on the basis of the rather large temperature change in the liquid in contact with the specimen accompanying the changes in pressure, for if that were the case, we would expect only the glass to be affected. Neither can it be explained on the basis of a differential compressibility of the solid modification of water and the glass or quartz, for no solid modification is known for alcohol or ether at these pressures and temperatures.

The fact that in cases where the glass or quartz has water on one side and oil on the other, only the side in contact with water is shattered, eliminates the possibility of the fracturing being due to a compressibility hysteresis effect of the glass or quartz being under extreme pressures. This is further demonstrated by the fact that, if glass or quartz pressure windows 4 mm thick and 12 mm in diam are mounted over a 6-mm-diam opening and subjected to a very high pressure, say, of 125,000 to 500,000 psi, they can be bent to a radius of curvature of 11 cm and returned without fracturing. This has been done with glass as many as 10 times with a single window, and with quartz as many as 4 times.

The most probable explanation of the fracturing of these materials, after having been subjected to pressures while surrounded by water, ether, or alcohol, is that the liquid, while compressed, actually penetrates the glass or quartz; then, as the pressure is released, the cohesive forces of the glass or quartz are not great enough to retain the liquid under the compressed condition. In the case where the pressure is dropped immediately, the liquid has not had sufficient time to penetrate the surface, and in the case where the pressure is allowed to go down very slowly, the liquid escapes without producing undue strain in the glass or quartz. These results can be summarized as follows:

(*a*) Little or no breakage occurs if insufficient time is allowed for the liquids to penetrate.

(*b*) Breakage occurs as the pressure is released rather than when it is being built up or retained at a high pressure.

(*c*) Little or no breakage occurs if the pressure is allowed to drop slowly enough to permit the gradual escape of the liquid which has penetrated the surface.

(*d*) No breakage occurs if liquids of relatively large molecules or a high viscosity are used, such as oil and glycerin.

(*e*) Fracturing is determined by the type of liquid in contact with the specimens and not by the pressure alone, as is shown when different liquids are on opposite sides of the same piece of glass or quartz; in this case pressures are obviously the same.

The results of the present investigation seem to indicate very clearly that the phenomenon of cavitation erosion is closely related to the one just described.

Studies on Cavitation Erosion

Cavitation-erosion studies were made using a magnetostriction oscillator and gray-cast-iron test specimens.

If cavitation erosion is a result of the penetration of liquids into the pores of the metal and their subsequent escape carrying some of the metal with it, it would be expected that the erosive action of water would be much greater than that of alcohol or ether, and that glycerin and paraffin oil would produce little or no effect. It is found that this is in accord with experimental results. Now, if the cavitation-erosion action were due primarily to a fatigue effect of the metal surface as a result of its being repeatedly stressed it would be expected that mercury would have a very large erosive effect since the forces involved would be much greater than in the cases of the other liquids, whereas, at moderate amplitudes it produces less erosion than water.

Fig. 2 Slightly Eroded Surface of Gray-Cast-Iron Specimen, Also Showing Fatigue Cracks; Vibrations Applied Perpendicular to Surface

In the case of cavitation erosion of iron samples by means of water, the iron that is removed from the surface of the test piece is found in the water as iron hydroxide. In an attempt to determine whether this hydrolysis of the finely divided particles of iron takes place as a part of the cavitation-erosion process or whether it takes place after the particles of iron have been dispersed in the water, experiments were run in which absolute alcohol was substituted for water. In this case the iron was found present in the alcohol in the form of finely divided metallic iron rather than the hydroxide. This, of course, does not prove that in the case of water, the hydrolysis does not take place on the surface of the metal but it does provide an eroded metal surface which is free from iron hydroxide. In addition to the normal erosion of the surface of a slightly eroded specimen, numerous cracks can be seen in the photomicrograph of the eroded surface, Fig. 2. These are probably fatigue cracks which have started to develop. It is possible that this method will give a means of determining the extent to which fatigue enters into cavitation erosion of this type.

Experiments With Magnetostriction Oscillator

Gray-cast-iron specimens were subjected to three different sets of conditions, in all cases using the magnetostriction oscillator as the source of energy. A nickel tube about 1 ft in length was used to give a normal frequency of 8000 cycles per sec.

Condition 1 The specimens under investigation were vibrated in a direction perpendicular to the surface being studied. A typical eroded surface is shown in Fig. 2.

Condition 2 The specimens under investigation were vibrated

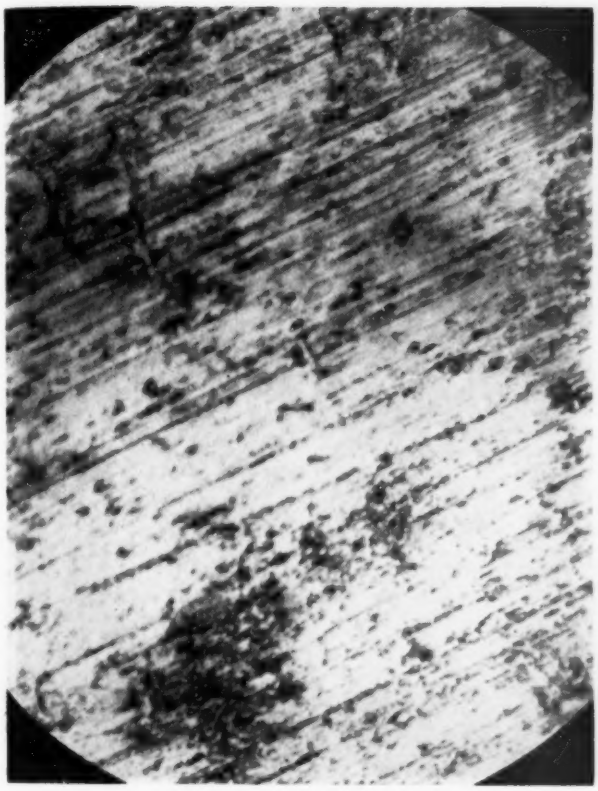

FIG. 3 ETCHED SPECIMEN AFTER HAVING BEEN VIBRATED IN A DIRECTION PARALLEL WITH SURFACE BEING STUDIED

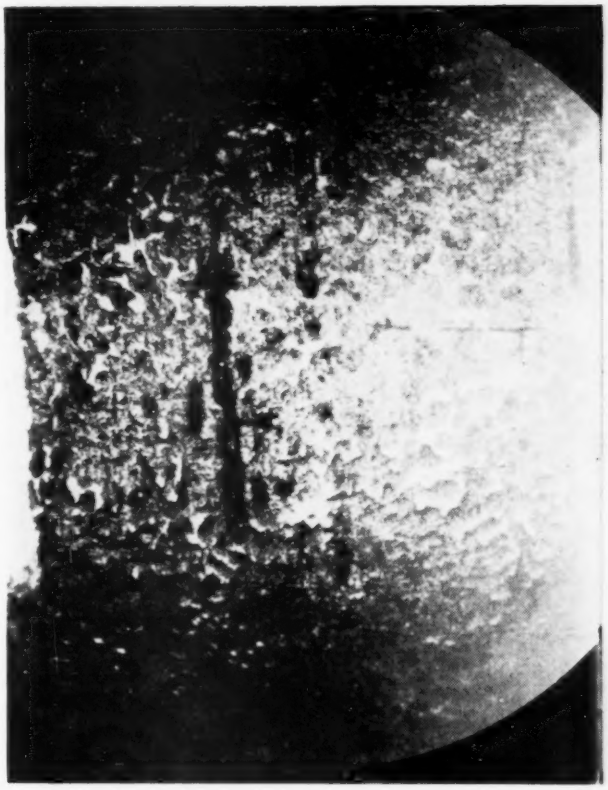

FIG. 4 ETCHED SPECIMEN OF GRAY-CAST-IRON TUBE AFTER BEING SUBJECTED ALTERNATELY TO COMPRESSION AND TENSION FORCES ACTING PARALLEL WITH THE SURFACE

parallel with the surface being studied. The results, Fig. 3, were very similar to those obtained under condition 1.

Condition 3 The specimen was stationary but was subjected to compression and tension forces acting parallel to the surface being studied. This was accomplished by silver-soldering a section of gray-cast-iron tube in at the center of the nickel tube so that, as the tube vibrated longitudinally, the iron specimen formed its node.

Under these conditions, there is still a very marked erosion of the surface, but in this case a more general erosion of the surface is produced rather than a concentration of the effect in deep cavities, Fig. 4.

An examination of the surface of the vibrating specimen under condition 1 was made with a microscope, illuminating the specimen with a stroboscopic light source. Under these conditions, the formation and collapse of small cavities in the water near the metal surface could be observed. These cavities seemed to reform in the same place on the surface of the metal rather than assuming a different random distribution for each cycle.

In all cases where attempts were made to detect the presence of supersonic or near-supersonic vibrations in the liquid producing cavitation erosion, they have been found to be very intense.

What the magnitude of the maximum tension or compression force is, which can be produced in a compression wave, depends upon the medium through which the wave is passing. This maximum also depends upon the wave form or, in other words, the distribution of energy among the various frequency constituents composing the wave.

For a gas, it is apparent that the average pressure over a complete cycle must be equal to the measured pressure of the gas. There seems to be no theoretical limit to the maximum pressure, but it would seem that the minimum pressure would be zero and that it could never be negative in value. In solids it would appear that the maximum pressure is theoretically unlimited and that the greatest negative pressure would be the tensile strength of the material.

However, there is considerable experimental evidence to indicate that the maximum negative pressure or tension is a function of the frequency, or a function of the rate at which the tension is applied; and that it may exceed the normal tensile strength of the material, the high values being associated with the high rate of application.

In liquids, the situation is even more complicated than it is in either gases or solids. It is largely this difference that makes possible the phenomenon of cavitation erosion. The maximum pressure for liquids is more closely related to that of solids, while the minimum or negative pressure resembles that of a solid up to a certain point; from then on it is similar to a gas. This sharp transition is the point at which the continuity of the liquid is broken and a cavity is formed. It takes place not at a zero pressure but at a negative pressure or tension which might correctly be called the tensile strength of the liquid; frequently, this may be several kilograms per square centimeter. Some experiments have indicated a tensile strength for water of several hundred kilograms per square centimeter.

In suggesting that the maximum pressure for compression waves theoretically may be infinitely large, the author is mindful of course that it would be practically impossible to produce an infinite pressure. However, illustrations of actual compression waves can be cited in all three physical states where these maximum pressures exceed 1,000,000 psi at the source of the disturbance. This is true notwithstanding the fact that the example for gas occurs, even though the average pressure is only a small frac-

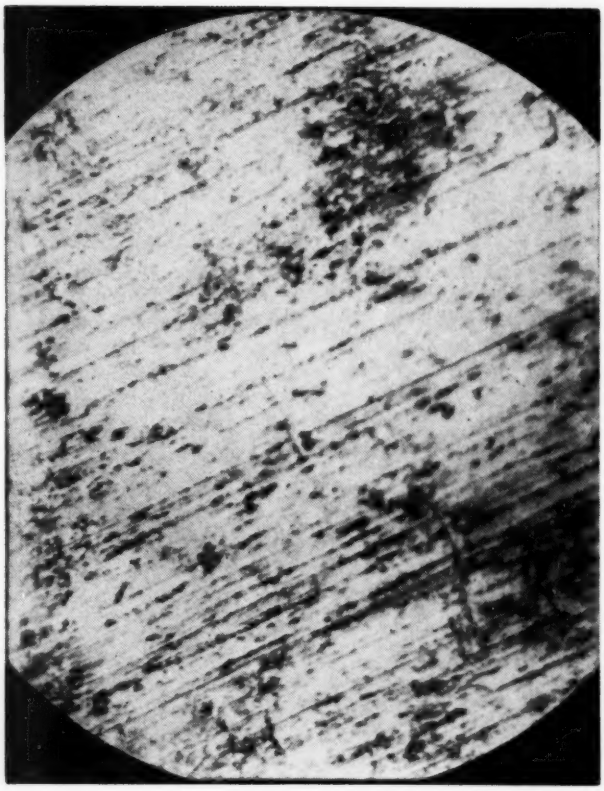

FIG. 5 SURFACE OF IRON SPECIMEN, SHOWING WIDESPREAD EROSION, AFTER BEING SUSPENDED IN WATER AND SUBJECTED TO COMPRESSION WAVE HAVING A FREQUENCY OF 8000 CYCLES PER SEC

FIG. 6 RESULT OF TREATING ONE HALF OF AN IRON SPECIMEN WITH OIL FILM TO PREVENT CAVITATION EROSION

tion of a millimeter of mercury. Reference is made to the compression wave set up, as particles of meteoric matter traveling with a velocity of 30 mps strike the very light upper atmosphere. At an altitude of about 100 miles, the gas pressure built up ahead of these tiny particles is in excess of 1,000,000 psi. Perhaps the nearest approach to those pressures, producing sound waves that are commonly heard by man, are developed by electrical discharges, such as lightning or discharges in the laboratory.

In the case of solids, pressures in excess of 1,000,000 psi are produced by such common things as striking two files together; the diamond of an emery-wheel dresser striking the grains of the wheel; or a high-powered-rifle bullet striking a hard object. Perhaps the most common example of liquid pressures approaching or exceeding 1,000,000 psi occurs when a cavity in a liquid is collapsed rapidly. Hence, this is the fundamental source of energy responsible for cavitation erosion.

FORCES PRODUCED DURING CAVITATION

Let us assume that we have a spherical cavity in water and that, due to the pressure on the water, this cavity is being collapsed.

Now, regardless of the size of the cavity or the rate at which it is being collapsed, if the water were incompressible the impact velocity of the walls of the cavity when they meet at the center would be infinity, therefore, the pressure produced would be infinitely great.

Since the water is not incompressible this is of course not true. There are two limiting factors: (1) The compressibility of the water produces some cushioning effect; (2) a thermal effect results from the compression. These two factors act in opposite directions and tend to offset one another. These effects are not

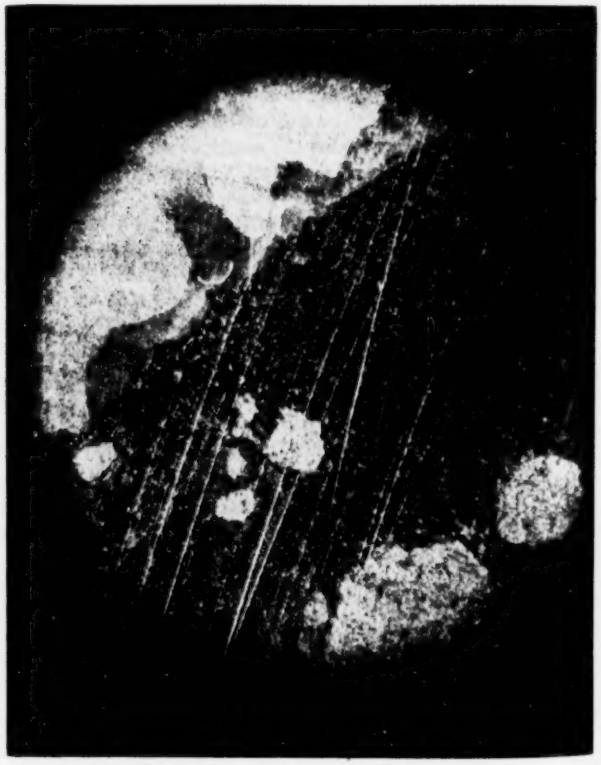

FIG. 7 WITH PARAFFIN OIL AS PROTECTIVE COATING, MANY SPOTS SHOW WHERE FILM WAS PENETRATED ALLOWING EROSION TO OCCUR

excessively large until a pressure of about 8500 atm is reached. At that pressure, if the temperature did not rise, the water would compress to about 60 per cent of its original volume and the water would change to a solid known as "ice six." Ice six has a melting point of 70 F at 8500 atm. Due to the sudden development of an extremely high pressure, it would be expected that a very high temperature would be developed. The elapsed time during which this extremely high pressure is being built up and again reduced probably does not exceed 10μ sec, but it may be repeated more than 10,000 times per sec at the same point.

Such conditions are effective in producing cavitation erosion only when they take place at the surface of the metal. However, the collapse of such a cavity out in the body of a liquid sets up a supersonic or near-supersonic compression wave in the water which travels with a velocity of about 5000 fps. If the amplitude of this compression wave as it strikes the walls of the containers is very large, a number of cavities will be formed at the metal-water interface.

Experimental Evidence of Cavitation Forces

In order to test this experimentally, an iron specimen was suspended in water and a compression wave, having a frequency of 8000 cycles per sec, was introduced into the water by means of a magnetostriction oscillator. The erosion produced on this specimen, as shown in Fig. 5, was widespread over the entire surface of the specimen.

If this is the correct mechanism of cavitation erosion, it would be expected in general that the more porous materials would be most readily affected. This in general is found to be the case, but the brittleness of the material cannot be overlooked. It will be recalled that, in the case of fracturing the glass or quartz specimens by subjecting them to a high hydrostatic pressure and subsequently releasing that pressure, water was most effective, ether next, alcohol next, glycerin producing fractures but rarely, and paraffin oil not at all. A careful examination of these results will show that both molecular size and viscosity play an important part. Water having the smallest molecule produces the greatest effect; the ether molecule, being considerably larger, produces a much less marked effect than water but somewhat greater than alcohol. Glycerin and ether were selected because of their relative molecular sizes and viscosities, the ether molecule being the larger, but having the lower viscosity. In spite of ether having the larger molecule, it is much more effective in producing fracture of the glass or quartz than is glycerin which has a smaller molecule but has a much greater viscosity. This, therefore indicates that the pores are relatively large as compared with these molecular dimensions, and that the glycerin does not enter because of its greater viscosity.

Also in the experiments on glass and fused quartz, it was found that, if a specimen had previously been subjected to pressure while immersed in paraffin oil, subsequent treatment in water

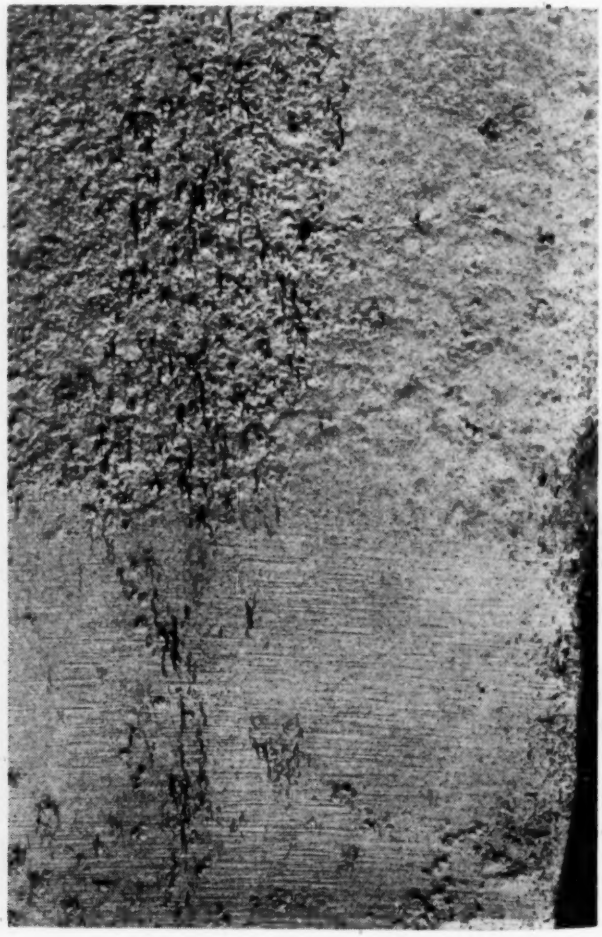

FIG. 12 ENLARGED VIEW OF ONE OF THE FRAGMENTS FROM THE HYDROGEN CYLINDER

would usually be less effective in producing fracture. It was therefore considered possible in some way to seal or fill the pores of the metal surface so as to prevent the cavitation-erosion action of water upon the surface, even though all other necessary conditions were present for producing erosion. Two identical specimens were prepared and one of them treated with a material which produces an absorbed molecular layer on the surface of the metal. This film produced a noticeable reduction in the erosion of the specimen. Another specimen was then prepared and one half of the specimen treated and the other half left in its original condition. In this case the oil film was somewhat thicker than on the previous specimen. The treated half of the specimen seemed to be completely protected against cavitation erosion for the duration of the experiment which was for 24 hr, or 500,000,000 cycles, whereas the other half of the specimen was quite badly eroded, Fig. 6. A similar series of tests were made in which paraffin oil was used as a protective coating instead of the film-forming material. The protection was found to be very much inferior to the first material. The protective coating in this case was penetrated at many points producing numerous eroded spots, Fig. 7.

Effect of Hydrogen on Cavitation Erosion

It is, of course, well known that a cylinder designed to withstand extremely high pressures will fail at a very much lower pressure, if, in addition to the liquid pressure, it contains considerable hydrogen. If a steel tube is filled at one end with water and at the other end with oil, and sufficient pressure applied, the failure will usually occur in the end of the tube containing the water, even though the pressure is applied through the end containing the oil.

Two pressure cylinders were constructed from the same bar of steel and received the same heat-treatment. Both cylinders were repeatedly subjected to pressures of approximately 400,000 psi. In one case, the cylinder contained only oil; and in the other case, a small rubber capsule containing zinc and sulphuric acid was suspended in the oil to generate hydrogen. Both cylinders were used under these conditions until they failed. The cylinder containing the hydrogen failed after it had maintained a pressure for a total time of less than 2 hr; whereas, the one containing no hydrogen had a service life of several months, during which time it was probably under pressure the equivalent of several days. After failure, these two cylinders were sectioned and deep-etched; Fig. 8 showing the one which contained no hydrogen, and Fig. 9 showing extensive cracks radiating from the inside surface of the cylinder which contained hydrogen. Subsequent experiments indicated that these hydrogen cracks may penetrate as much as $^1/_8$ in. into the cylinder wall in a few minutes with a pressure of only 30,000 psi, and that a similar effect takes place very slowly, even with gaseous hydrogen pressures of approximately 2000 psi.

Fig. 10 shows a 200-cu-ft hydrogen cylinder which failed after being in service for about 25 years. A careful examination of the walls of this cylinder shows that the inside surface is covered with small cracks, some of which extend as much as 25 per cent of the way through the cylinder wall. Fig. 11 shows six of these fragments undergoing magnaflux examination. Fig. 12 is an enlargement of one of the pieces. Hydrogen cylinders were then selected which had been in service about the same length of time, but which had not failed. Examination showed the inside surfaces to be in approximately the same condition as the one that failed, whereas, cylinders made at the same time and from the same batch of steel, but which had been in nitrogen service, were still in good condition.

In 1937, Fred R. Venton of the research testing laboratory, Crane Company, Chicago, reported results[3] on steam erosion of various alloys. Cavitation-erosion tests were run on a similar series of alloys with strikingly comparable results. In these results, it was found that a face-centered-crystal lattice offers very much greater resistance to steam erosion and cavitation erosion, and that there seems to be no correlation between hardness and erosion resistance. If the energy is not too great, lead and rubber resist cavitation erosion almost indefinitely, whereas glass, cast iron, and carboalloys are quite rapidly eroded.

Design Data

It is important that the data contained in technical papers be made readily available to designing engineers. In order to satisfy these needs of industry, this section of the JOURNAL will include a concise presentation of data and information drawn chiefly from papers previously published by the Applied Mechanics Division of The American Society of Mechanical Engineers.

The data are prepared by a subcommittee of the Applied Mechanics Division under the guidance of S. Timoshenko. This article contains data on the design of pipe.

Expansion of Formulas for Calculating Loads, Rotation, and Deflections of Quarter Bends and Tangents of Pipes

By A. S. McCORMICK,[1] SCHENECTADY, N. Y.

IN calculating the forces and moments due to thermal expansion on a run of pipe in three planes, made up of tangents and quarter bends, the greater part of the time consumed in the calculation has heretofore been spent in determining the correct direction of the various rotations and deflections. This was found to be especially true of the Karelitz-Marchant method, as previously published,[2] and other methods using the formulas of Hovgaard, Crocker, and McCutcheon.

These formulas are presented herewith in graphic form to show every possible position of quarter bend and tangent with respect to the axes X, Y, and Z, under the different loading conditions. This reduces possible error to a minimum inasmuch as, in working out the direction of rotation and deflection for the different loading conditions, it has been possible to check one condition against another. In the use of the formulas, it is merely necessary to locate the desired condition on the plates and copy the formulas so that the compilation of rotations and deflections, from one end of a pipe run to the other, becomes a more or less mechanical process.

Using this set of tables, it has been possible to reduce the calculation of a three-plane pipe problem from a task of several days to one of approximately a day and a half, a calculating-machine operator doing the arithmetical work.

The accompanying illustrations show the different cases in perspective. At the top of each panel, covering a loading condition, the formulas for rotation and deflection are given, the formulas in each case being numbered. The direction of rotation is given for each case, referred to the positive ends of the axes of the plane in which it occurs, followed by the number of the formula for the numerical value. The deflection of each case is given with respect to the axis along which it occurs, followed by the number of the formula for the numerical value and a letter denoting direction on the axis along which it occurs. Each section of each panel covers four cases; the tangents and quarter bends are assumed to be anchored at the intersection of the axes X, Y, and Z.

Direction of deflection

B = back ..... } ΔY
F = forward .. }

R = right .... } ΔX
L = left ..... }

U = up ..... } ΔZ
D = down .... }

X, Y, Z = rectangular axes through fixed end of quarter bend or tangent

F = force acting on free end of tangent or quarter bend

M_b = bending moment acting on free end of tangent or quarter bend

M_t = turning moment acting on free end of tangent or quarter bend

I = moment of inertia of pipe section

E = modulus of elasticity of material, corrected for working temperature, according to equation

$$E_t = E_{32}\left[1 - \left(\frac{T - 32}{1700}\right)^2\right]$$

where

E_t = modulus of elasticity at T deg F

E_{32} = modulus of elasticity at 32 F

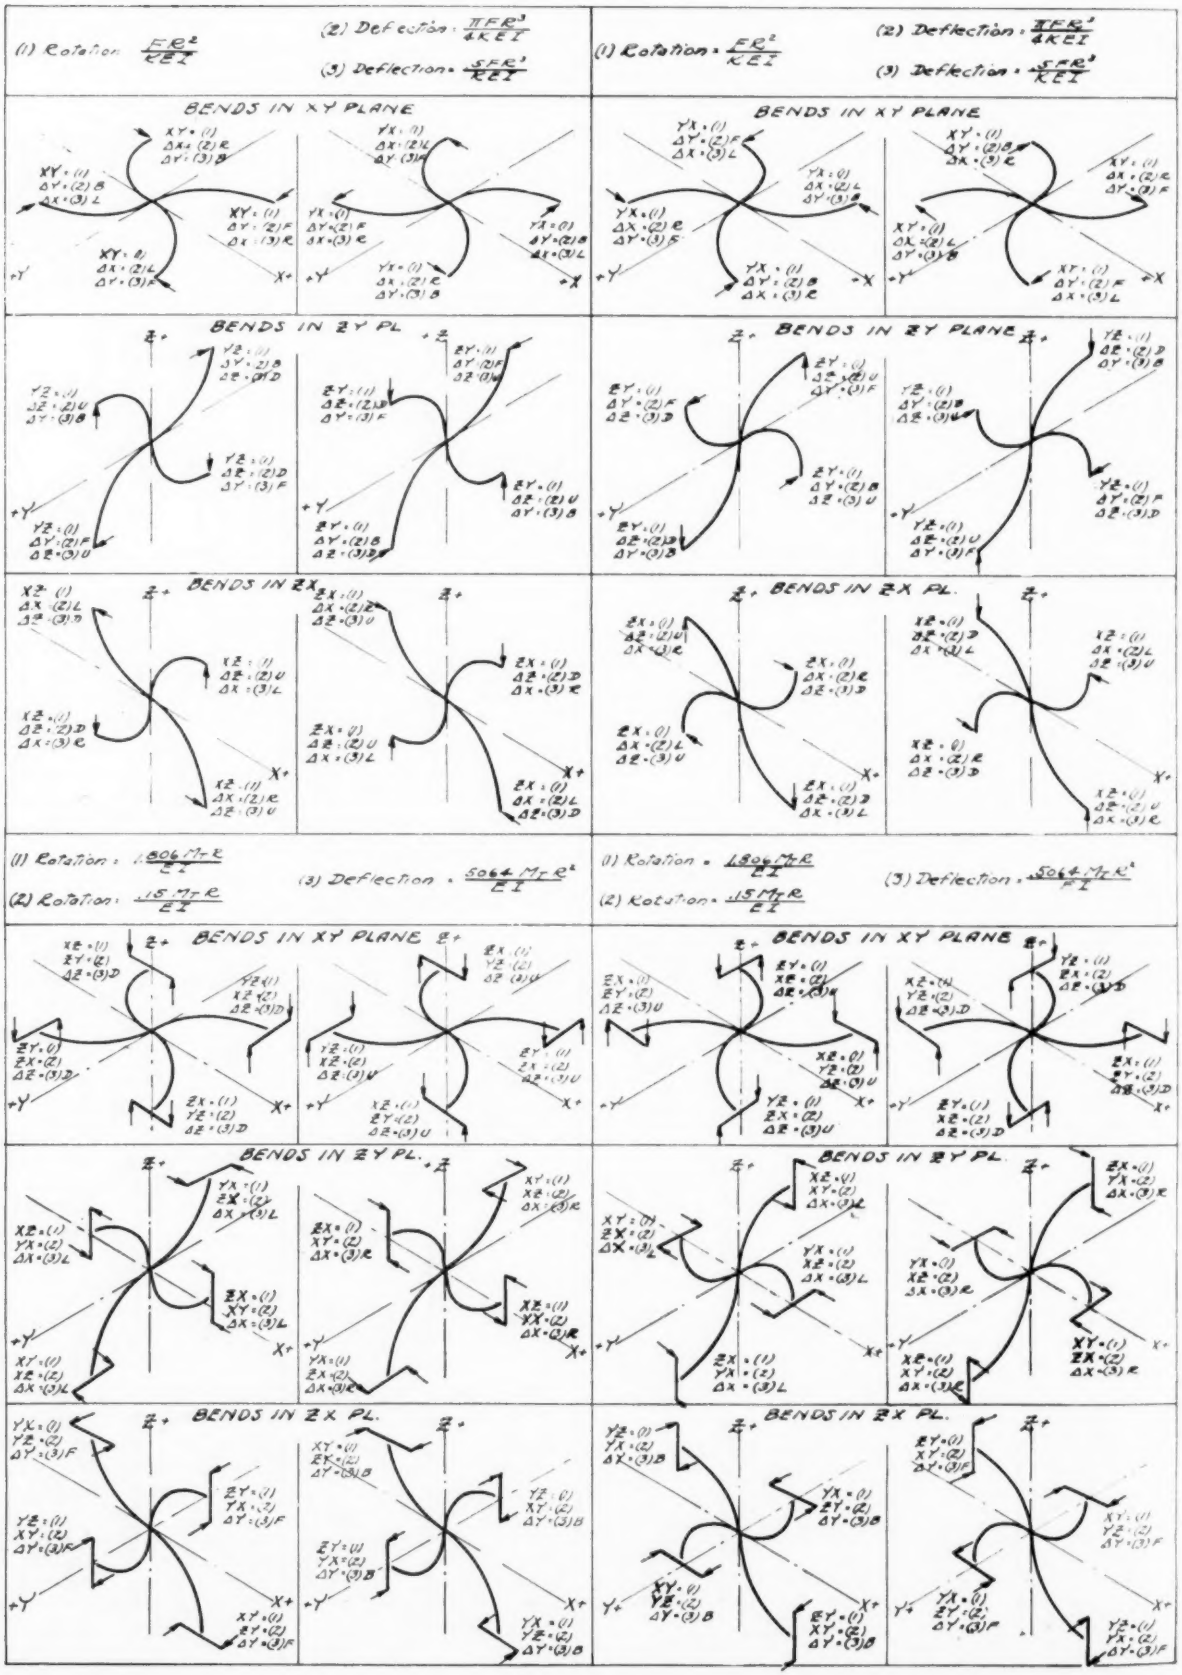
K = rigidity multiplication factor $= \dfrac{1 + 12\,h^2}{10 + 12\,h^2}$

where

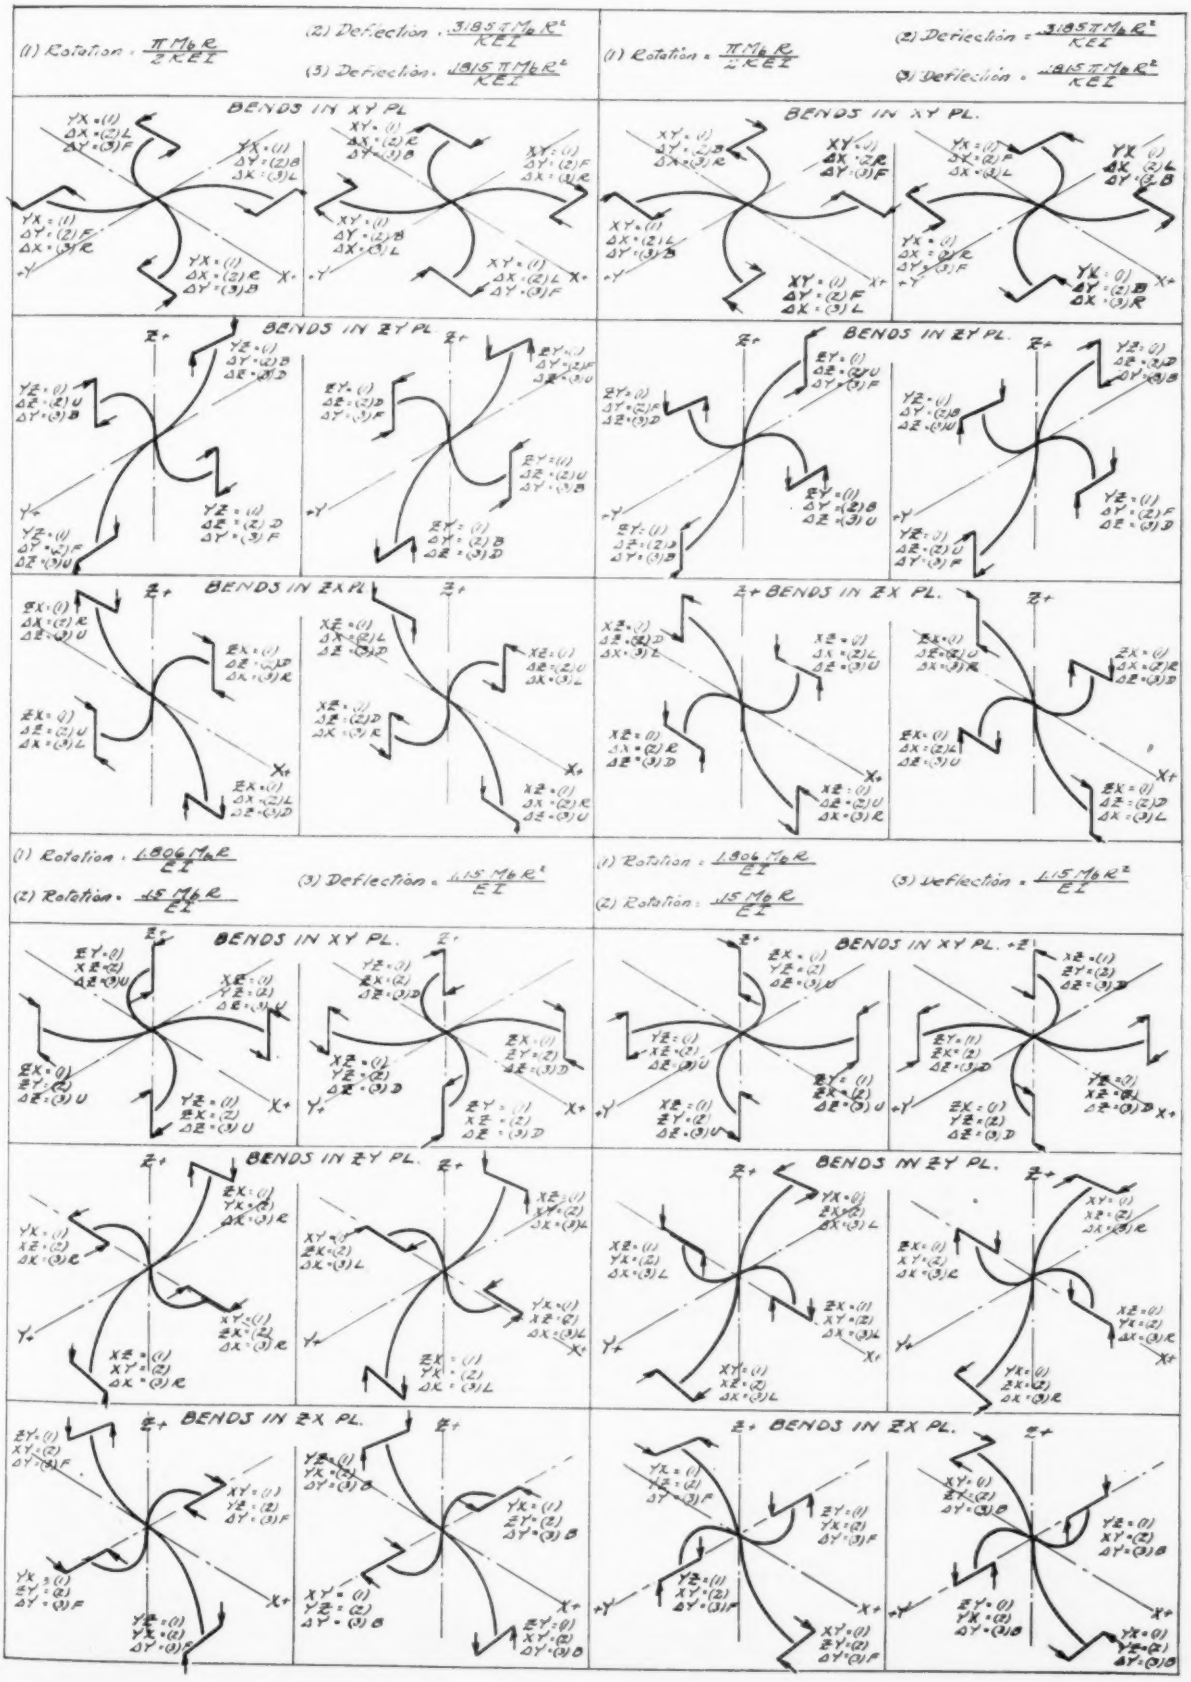
$$h = \frac{tR}{r^2}$$

t = thickness of pipe wall

R = mean radius of pipe bend



r = mean radius of pipe wall



No basic change has been made in any of the formulas presented in the article cited.[2] Well-known formulas have merely been expanded to facilitate their use and to reduce labor and probability of error as much as possible.

Discussion

Effects of Surface Finish on Journal Bearing Performance[1]

C. R. Lewis.[2] Work on the subject matter of this paper is being done in the laboratories of the Chrysler Corporation which confirms in general the results of the research at the Massachusetts Institute of Technology. However, this work has brought out several points which the authors do not mention and which indicate some new reasons for his results.

The Chrysler work has indicated that, when surfaces of dissimilar roughness are run together, the results tend to be characteristic of the rough surface. This result throws some light on the observation in the paper that comparatively little increase in load-carrying ability is found below 15 microinches, as the babbitt bearings were reported to measure from 6 to 10 microinches.

It has also been found that the minimum of the friction curve tends to be much more sharply defined for smoother surfaces. Some indication of this condition is found in Fig. 6 of the paper. It is more evident when harder materials are used, as the soft babbitt tends to flow either plastically or due to melting when the oil film fails. This flow may change either the surface smoothness or the clearance ratio, and may, as the authors found, produce a succession of minima in the friction curve. In less definite cases, it produces a broadness in the minimum of this curve. The broadening of the minimum, because of surface roughness, is believed due to the introduction of turbulence in the oil film before actual rupture takes place. The hydrodynamic analyses, predicting the dependence of the friction coefficient on the quantity $S = ZN/P$, are based on the assumption that the oil in the lubricant film is in a condition of streamline flow at all times. It seems reasonable that skin friction of the oil against a rough surface would disturb this streamline flow, so as to give a more gradual departure from full hydrodynamic lubrication than in the case of a smooth surface. This effect is found in curves A, B, and M of Fig. 6 of the paper.

A preliminary investigation of the effect of surface finish on oil-film thickness has been made in the Chrysler Laboratories. In this work, the bearing surfaces were a stationary-plane pivoted slider and a revolving-plane disk. The film thickness was calculated from a measurement of the electrical capacity between the slider and the disk. The results are shown in Fig. 1 of this discussion. Both the rough (30-microinch) and the smooth (2-microinch) surfaces gave film thickness agreeing well with those predicted from a formula given by Professor Karelitz.[3]

Confirming results of the second part of the authors' paper, we found momentary metallic contacts even at quite light loads of about 50 psi. The frequency of these contacts increased with load until, with the highest load used on the smooth surface, the surfaces were touching about 30 per cent of the time. The fact that these contacts are related to surface imperfections is indicated by the observation that most of them were confined to a 90-deg segment of the disk.

At the maximum load shown for the rough surface (150 psi), the surfaces were in contact about 40 per cent of the time. An attempt to increase the load caused the surfaces to seize. At this point, the measured thickness of the oil film was about 7 times the height of the surface irregularities expected on each surface from a profilometer reading of 30 microinches. However, this measured thickness was an average value for the entire surface and does not indicate the minimum thickness. At the highest load available for the smooth surface, the measured film thickness was some 30 times the height of the surface irregularities, and no signs of failure were observed. These preliminary tests indicate that, when rupture of the oil film occurs due to surface imperfections, the thickness of the oil film is roughly of the same order of magnitude as the height of the surface irregularities. This result suggests the mechanism by which the surface finish affects the load-carrying ability of a bearing.

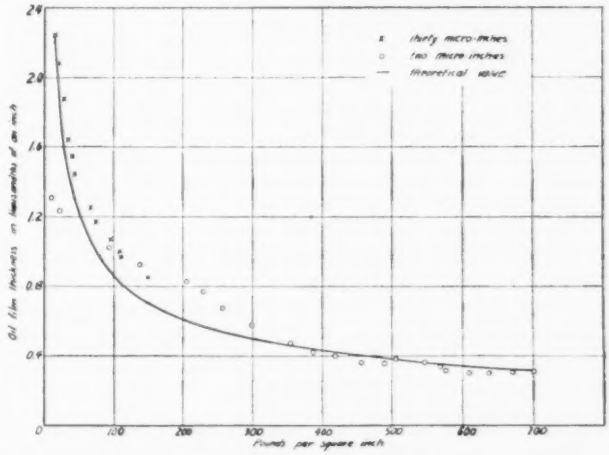

Fig. 1 Oil-Film Thickness Calculated From Measurement of Electrical Capacity Between Bearing Surfaces, Consisting of Stationary-Plane Pivoted Slider and Revolving-Plane Disk

L. M. Tichvinsky.[4] The fact that the authors determine the D/C ratio indirectly by measuring of μ, N, and P on the testing machine indicates that utmost precision has to be followed during such experimentation.

It is known that a ground surface may be wavy and at the same time very smooth. The waviness depends upon several factors such as the speed of the ground object and the grinding wheel, the feed, type of mounting, the bearing oil-film uniformity and carrying capacity, and also the skill of the operator. In this connection, it will be of interest to learn whether or not any waviness is being obtained when a superfinish method is applied.

The results of further investigations of this kind will be quite useful to bearing designers. Surface-friction relationships in the boundary region at loads encountered in industrial machines when starting or stopping are still unavailable.

Authors' Closure

Mr. Lewis' conclusion that the reason for the comparatively small increase in load-carrying capacity below 15 microinches is the roughness of the babbitt bearings themselves is interesting

[1] By J. T. Burwell, J. Kaye, D. W. van Nymegen, and D. A. Morgan, published in the June, 1941, issue of the Journal of Applied Mechanics, Trans. A.S.M.E., vol. 63, p. A-49.

[4] U. S. Naval Engineering Experiment Station, Annapolis, Md.

but does not seem very probable. When metal-to-metal contact first occurs, the shaft wipes the much softer babbitt and imparts to it a surface having the same roughness as the shaft. Subsequent performance and ultimate seizure will be governed by this final roughness rather than the initial one. This effect may possibly be responsible for the fluctuating character of the minimum of the friction coefficient curve I in Fig. 7 of the original paper, although we are more inclined to attribute it to the change produced in the D/C ratio. The suggestion that the broadening of the minimum of the curves for rough surfaces is due to turbulence is an interesting and novel one. A further investigation of this idea should be undertaken.

Mr. Lewis' measurements of the oil-film thickness for a hydrodynamically lubricated plane slider show good agreement with the theoretical curve. From these results, he concludes that the rupture of the oil film, and hence the limit of stable bearing operation, occurs when the thickness of the oil film is of the same order of magnitude as the height of the surface irregularities. This conclusion is most important in substantiating the already postulated mechanism of what occurs when the limiting value of $\mu N/p$ is exceeded, namely, that metal-to-metal contact of the high spots on the two surfaces takes place with resultant failure of the oil film.

In answer to Mr. Tichvinsky's question, it is quite unusual to obtain any sort of waviness from a superfinishing operation, and waviness on a previously ground surface is generally removed. This is due to the small inertia and relatively large cutting area of the superfinishing stones. We agree that it is important to distinguish waviness from roughness, and this difference may be very significant in the region of boundary lubrication.

An Eddy-Current Method of Flaw Detection in Nonmagnetic Metals[1]

S. L. Burgwin.[2] The writer's limited experience in detecting flaws in nonmagnetic materials has indicated some of the possibilities of the eddy-current method of flaw detection, so it is with considerable interest that the present paper has been studied.

When the author claims a type of search unit which is universal, presumably he means universal in the sense that it can be used with almost any conducting material, not in the sense that it can be used for all sizes and shapes of metallic objects. The writer has in mind a particular problem which came up some years ago, wherein it was desired to check small contacts made up of two materials to be sure that they would not split apart. An eddy-current method of test was devised which has since operated very successfully. However, the size and shape of these contacts were such that it would be impractical to use the type of instrument developed by the author.

In other applications his device could be used successfully although, for production applications, practical use would probably require some modification of the design of the test unit for each application. Some years ago the writer developed a search unit of somewhat different design but having approximately the same underlying principle which was used to detect flaws in sheets. The device was successful enough, but scanning large sheets by hand was found to be rather slow and tedious. The successful use of such apparatus on large objects for other than trouble shooting would probably depend upon whether the scanning could be made automatic.

As to the practical use of the unit described in the paper, there are several points of interest which it is believed were not covered in the paper. For instance, if the axis of the search unit is not kept normal to the surface of the test material, as may occur when the surface of the test material is wavy or dirty or when testing objects with rough or uneven surfaces, would a voltage not be generated in the pick-up coil? If so, how serious is this effect? In the paper some mention was made of the rapidity of scanning. Could the author give some concrete idea of how long it would take to scan a sheet of stainless steel 3 ft square and perhaps $^1/_2$ in. thick?

H. J. Roast.[3] A paper such as this, which assists us in the discovery of latent flaws in metal articles, is of considerable value. The writer wishes to inquire whether or not this method will indicate the following: (*a*) Internal dross areas occluded in metal castings; (*b*) Gas holes occluded in metal castings.

The writer is a metallurgist dealing primarily with the manufacture of castings, rather than a physicist whose interest lies in physical phenomena of all kinds. The question from this point of view is whether the lack of continuity of a dross area or gas hole would prevent its reacting to the magnetic field in a manner similar to that of a continuous crack.

We have recently had bronze castings, weighing about $^1/_4$ lb, X-rayed. At the moment, the requirement is for each casting to be X-rayed and the price quoted is $5 each. This is mentioned because it will be obvious that any method which would definitely show up dross areas or gas holes in a more economical way would be highly desirable.

The metal in question is manganese bronze, essentially 60 per cent copper, 40 per cent zinc, with displacement of the zinc of 1 per cent of aluminum, iron, and manganese.

If the method is applicable to the points raised, would it be possible to locate roughly the areas in regard to the various configurations of the casting?

Author's Closure

Many practical matters must be considered in applying the eddy-current method to the location of flaws in a group of identical metallic objects. In general, a jig is employed to hold the exploring head in a suitable and reproducible manner so that the scanning process may proceed regularly and automatically. Full attention can then be directed to reading the indicator if automatic recording is not employed, or if the detection of gross flaws alone is desired. The use of a jig maintains a proper position of the head, and a slightly wavy or dirty surface produces no systematic indication. The scanning rate with apparatus, operating on commercial frequencies, is low, but not so low as to limit its usefulness. The area examined in a given time depends, of course, upon the size of the exploring head, the exciting frequency, and the degree of overlap. It is easily possible to examine 9 sq ft of $^1/_{32}$-in. stainless steel and make a permanent record of the test in less than 4 min.

Our tests of the method show that it may easily be adapted to the location of voids or dross areas in a casting if these are within $^1/_2$ in. of the surface, and if the casting is not too complicated. By employing properly designed scanning jigs and actual records of the electric currents, it is believed that much could be learned about moderately complicated castings.

Although the basic principles outlined in this paper are still employed, various improvements have been adopted recently which add considerably to the usefulness and convenience of the method.

High-Speed Tension Tests at Elevated Temperatures—II and III[1]

W. N. FINDLEY.[2] The authors have used an ingenious method of recording the stress-strain curve from a high-speed tensile impact machine, and it is interesting to note the oscillations resulting from the impact. In connection with this disturbance the writer would like to describe a high-speed testing machine which he designed to avoid the oscillations resulting from impact loading. This machine was built while the writer was a McMullen research scholar under the direction of T. R. Cuyken-

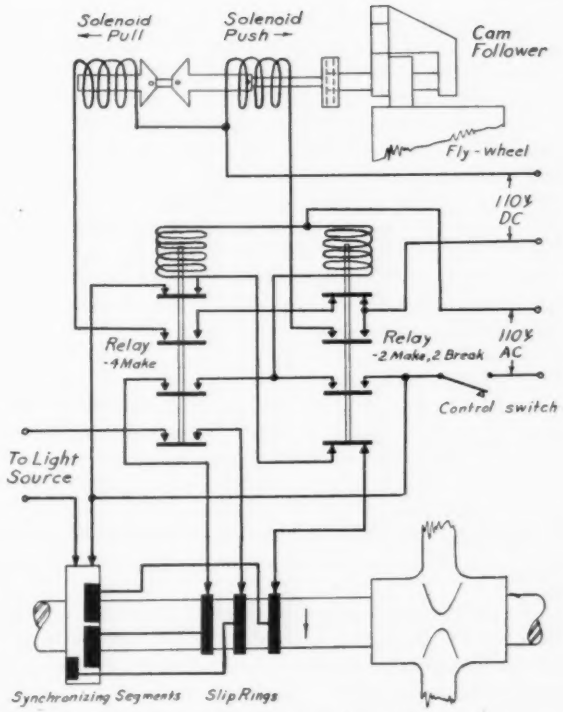

FIG. 3 SYNCHRONIZING APPARATUS

dall in the College of Engineering, Cornell University, and used in connection with a study of the photoelastic properties of Bakelite BT61893 under high-speed loading.[3] As used for this work the machine was designed to produce pure bending of a bar of the transparent material, but it could equally well be designed for tension or compression. The loading time obtained by this machine was of the same order of magnitude as that obtained by the authors. Oscillations resulting from impact or other nonuniform motion were avoided by using constant acceleration instead of constant velocity of crosshead motion.

The mechanism used to produce constant acceleration of the crosshead consisted of a plate cam, Fig. 2, mounted on the cylindrical surface of a 25-in-diam flywheel. A roller follower, Fig. 2, transmitted the motion of the cam to the specimen. The cam was formed in such a way that a constant velocity of the flywheel would produce a constant acceleration of the moving head. The cam follower consisted of a double row enclosed ball bearing which could be moved axially by two solenoids (electric magnets) Fig. 1. The outer race of the bearing was in rolling contact with the cam, Fig. 2.

The motion caused by the cam was transmitted through the roller follower and its shaft to a yoke which was fastened to the moving head of the machine. The unit consisting of the moving head, the roller follower, and its shaft was mounted in sliding ways which permitted vertical motion only.

Several revolutions of the flywheel were required to bring it up to speed. During this time the roller follower was in the outer extreme position in the yoke, Fig. 2*a*. In this position the cam passed under the follower shaft but the follower did not touch the cam. When it was desired to test the specimen the control circuit, Fig. 3, was closed, and by means of synchronizing segments and relays a solenoid was caused to pull the cam follower into

[3] "The Fundamentals of Photoelastic Stress Analysis Applied to Dynamic Stresses," by W. N. Findley, Ninth Semi-Annual Meeting of the Eastern Photoelasticity Conference, held at Cornell University, May 13, 1939; published by the College of Engineering, Cornell University, Ithaca, N. Y.

the operating position, Fig. 2*b*, and the test was performed. Immediately after the cam performed its function another solenoid pushed the cam follower back into the running position before the cam came around a second time. The horizontal motion of the follower shaft was controlled by the solenoids through a sliding finger so as not to interfere with the vertical motion of the loading head, Fig. 1. The circuit diagram, Fig. 3, shows provision for synchronizing other apparatus with the test such as a high-speed camera as in the case in which the apparatus was used.

L. H. Fry.[4] Study of this paper leads to a question as to the method used for measuring the strains in the so-called constant-strain-rate machine shown in Figs. 2 and 3 of the paper. These illustrations indicate that the strain is recorded by the rotation of the drum H which is turned by a string drive I. This string drive is shown to be attached to the heads of the testing machine and not to the test specimen itself. Under these conditions, the rotation of the drum measures the separation of the jaws of the machine, but there is no assurance that the separation of the jaws is directly proportional to the increase in the gage length of the specimen. This may be the case during plastic extension, but is almost certainly not so during the elastic stretch of the bar.

The writer has shown[5] that, during the plastic stage of a tension test with the testing-machine crosshead moving at a constant speed, the gage length of the specimen is stretched at a continually increasing rate. That is to say, the ratio of strain of specimen to crosshead travel increases rapidly until the yield point is reached. Therefore, it follows that, in the elastic range, the measurement of the crosshead travel cannot be used as a means of determining the rate of strain of the specimen.

The authors are mainly concerned with ultimate strengths, and it is probable that rate of travel of the head and rate of strain are more nearly equal at the end of the plastic stage than they are in the early period of the elastic stage. However, in all specifications of Committee A1 of the A.S.T.M. where an extensometer is used, it is required to be attached to the specimen and not to the head of the testing machine.

C. W. MacGregor.[6] This paper is particularly important since it represents a major extension of our knowledge in several directions. The range of testing speeds has been increased over those formerly reported and, at the same time, a very complete picture is given of the effects of temperature over this wide velocity range. The marked increase of the ultimate strength of copper at 1000 C of about 1000 per cent in a speed range of 10^8:1, as compared to 25 per cent at room temperature for the same increase in testing speed shows the great importance of strain velocities at elevated temperatures.

The writer is especially interested in Part III of the paper in which attempts are made to predict the shape of the necked-down tensile-test bar using various assumed stress-speed laws, such as the viscous and power function speed expressions. With certain modifications, it would appear possible also to predict the shape of the necked-down bar at room temperature. The writer would like to ask if any attempts were made to apply Ludwik's logarithmic speed law $\sigma = \sigma_0 + a \log V/V_0$, which holds at room temperature, to the problem of predicting the shape of the necked-down bar under these conditions?

Authors' Closure

The suggestion made by Mr. Findley is appreciated. While it seems attractive when used in cases in which the displacement between the two heads of the test specimen is essentially an elastic one, it must somewhat be questioned whether the method suggested by Mr. Findley has similar advantages when used in cases in which, on the contrary, this distortion is of the plastic nature. It should be noted that the dynamic system with which Mr. Findley is concerned in his rapid photoelastic tests, made with bakelite or celluloid in the elastic range, is far simpler than the one which presents itself in the tests described by the authors. It must be remembered that in these tests the system consists of a combination in series of a very stiff elastic spring (the force-measuring bar) and of a plastic system, namely, the test bar. In the first case, the resistance is known to be proportional to its own extension. However, the inner resistance in the test bar is not only unknown, but it is known to depend at low temperatures both on the strain and the rate of plastic strain, and at high temperatures on the rate of plastic strain. Since this latter is admittedly the most important variable, it was deemed advantageous to run our tests so that in a first approximation this variable was kept constant during a tension test. In other words, it was preferable to move the heads of the test bar with a constant velocity rather than, as Mr. Findley suggests, with a constant acceleration. Admittedly, this procedure had the disadvantage of exciting elastic oscillations because of the elasticity of the force-measuring bar and of the test bar. The diagrams which were published in the paper seem, however, to prove that the oscillations did not seriously affect the results, at least not within the limits of speeds which were used. The consequence of running a test under the condition specified by Mr. Findley would be that, during a test, the rate of plastic strain would increase continuously with the time or with the extension of the test piece.

While it is believed that the simple string device to which Mr. Fry refers was sufficiently accurate for recording plastic strains, its use is considered objectionable when exact records of small strains of the order of magnitude of the elastic strains are to be observed. For the intended comparison of the plastic rates of stretching at large strains, however, this primitive method for measuring strains is entirely satisfactory. It must be noted that an error of 20 or 30 per cent in the strain rate would shift the curve representing the speed law in the semilogarithmic plots (such as the ones shown in Figs. 9 to 11, 13, and 15 of the paper) by an insignificant amount considering the enormous range of the speeds.[7]

Since Mr. Fry brought up this point in his discussion, it is perhaps in order to add one or two remarks concerning what has been called in the paper "a constant-strain-rate test." If the length l between the shoulders of a test bar increases uniformly with time t, the true rate of straining within the cylindrical length l

$$\frac{d\bar{\epsilon}}{dt} = \frac{1}{l}\cdot\frac{dl}{dt} = \frac{d}{dt}\log_e\frac{l}{l_0} = \frac{d}{dt}\log_e(1+\epsilon) = \frac{1}{(1+\epsilon)}\cdot\frac{d\epsilon}{dt}$$

must decrease if dl/dt = constant in the same proportion as l increases. However, the curve for the speed law is changed to a very minor degree when instead of $d\bar{\epsilon}/dt$, $d\epsilon/dt$ is maintained constant during the tests.

[7] By measuring the changes in length by various independent methods, it was ascertained that errors in the strain measurements were of the order of 1 to 2 per cent. Since the string device records the relative displacement between the reinforced portions beyond the shoulders of the specimens for obtaining the value of the strain ϵ in the cylindrical portion of the test bar, a correction factor had to be introduced which was found by calibration for each of the investigated metals.

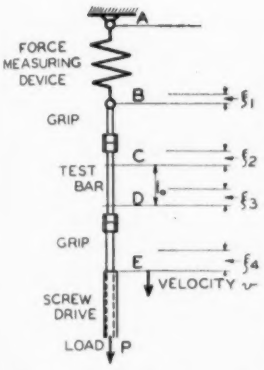

FIG. 4 TENSION MACHINE

With reference to Fig. 4 of this closure, which is a sketch of a mechanism for pulling a test bar, we wish to investigate the relation connecting the strain rate $d\epsilon/dt$ as measured in the gage length l_0 of the cylindrical test bar and the velocity v with which the lower head of the machine moves. The mechanism of a screw-driven tension machine was assumed, similar to the one described in the paper (Figs. 2 and 3), AB representing the force-measuring device, BC the upper grips, including the head of the test bar, CD the cylindrical portion of the test bar, and DE the lower grips. Assuming that the displacements of the points A, B, C, D, and E are 0, ξ_1, ξ_2, ξ_3, and ξ_4, respectively, we have for the increases of the lengths[a] the following:

In the force-measuring device (Fig. 5).....	$\xi_1 = g_1(P)$
In the upper grip.....	$\xi_2 - \xi_1 = g_2(P)$
In the gage length.....	$\xi_3 - \xi_2 = G(P)$
In the lower grip.....	$\xi_4 - \xi_3 = g_3(P)$
For the motion of the lower head.....	$\xi_4 = vt$

where the expression $g(P)$ designates functions of the load P, and t is the time. By adding these equations we obtain

$$vt = g_1(P) + g_2(P) + g_3(P) + G(P) \quad [1]$$

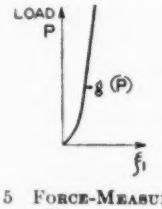

FIG. 5 FORCE-MEASURING DEVICE

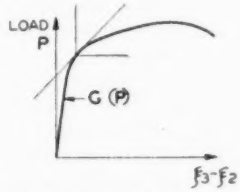

FIG. 6 STRESS-STRAIN CURVE

Since the strain is defined by

$$\epsilon = \frac{\xi_3 - \xi_2}{l_0} = \frac{G(P)}{l_0} \quad [2]$$

where $G(P)$ represents the conventional stress-strain diagram (Fig. 6 of this closure) of the material of the test bar, we have for the rate of strain

$$\frac{d\epsilon}{dt} = \frac{1}{l_0} \cdot \frac{dG}{dP} \cdot \frac{dP}{dt} \quad [3]$$

which equation connects the strain rate $d\epsilon/dt$ with the rate of loading dP/dt. Expression $dG/dP = G'(P)$ represents the slope of the stress-stain curve, Fig. 6. After differentiating Equation [1] with respect to the time t, and after eliminating dP/dt, we find that

$$\frac{d\epsilon}{dt} = \frac{v}{l_0} \cdot \frac{1}{\left[1 + \dfrac{(g_1' + g_2' = g_3')}{G'}\right]} \quad [4]$$

From this expression, the rate of strain $d\epsilon/dt$ can be computed for a given velocity v of the lower head of the testing machine provided sufficient observations were made for obtaining the values of the three functions g_1', g_2', and g_3'. Equation [4] is valid for uniform stretching, but not for discontinuous yielding, since in this latter case ϵ is not completely defined by means of Equation [3]. The g' terms are the derivatives dg/dP, i.e., the slopes in the curves $\xi_n - \xi_{n-1} = g_n(P)$. Some care should be exercised in their evaluation in the case when slipping occurs in the wedges or in the grips.

We can conclude from Equation [4] that while the looseness in the grips is gradually taken up under small loads the rate of strain $d\epsilon/dt$ cannot yet remain constant at a head velocity v = constant. The same is true due to slipping of the wedges or when gradually an elastic contact is established in the grips. However, in a machine with a strictly linear and stiff characteristic, such as the one described in the paper we have g_1' = constant. After the grips have become tight $d\epsilon/dt$ soon tends to become a constant, while the head of the machine moves with a constant velocity v. In other words, this device can well serve for running a constant-strain-rate test with a rate of stretching which for the larger strains is proportional to the velocity v of the head.

Dr. MacGregor mentions the possibility of further practical applications of the theory of the necking of bars to cases frequently observed. The few examples treated in the paper were selected with a view to describing simultaneous stretching and contracting of bars having variable cross sections, under the simplest assumption which could be made, namely, that stress would depend only upon the rate of strain. At low temperatures (room temperatures), it is not yet clear whether such a dependence would be sufficient for describing the necking in bars, since, at low temperatures, stress is a function of the plastic strain and of the rate of strain, which fact probably complicates the analysis further.

[a] The authors are indebted to P. G. McVetty for having called attention to the fact that the late Prof. T. Hammond Smith had separated the relative motions in the moving parts of a testing machine in a similar manner by plotting the ξ_1, ξ_2 . . . . in function of the time t; refer to "The Rate of Elongation in Tension Tests," by T. H. Smith, Proceedings of the American Society for Testing Materials, vol. 27, 1927, pp. 507–519.

Note on Calculation of Influence Surfaces in Plates by Use of Difference Equations[1]

V. P. JENSEN.[2] The author's theorem is a definite contribution to the literature on the engineering uses of difference equations. It materially extends the field of practical application of difference equations by making possible a rapid determination of the effect of moving loads on a slab.

The writer has applied the theorem to the problem of determining live-load moments at various points on skew-slab highway bridges with curbs.[3] Truck-wheel loads and spacings for the design of such bridges are specified by the American Association of State Highway Officials.[4] Since the positions of the wheel loads on the bridge will not coincide with the nodal points of the network used in the analysis, the advantages of an influence surface become apparent.

As an illustration of the practical application of the theorem, consider the bridge, shown in Fig. 1 of this discussion. A convenient network for the analysis of this bridge is shown in Fig. 2. The equation for the bending moment in the curb at point 4 is

$$(M_{curb})_4 = \frac{EI}{\lambda^2} (2w_4 - w_2 - w_7)$$

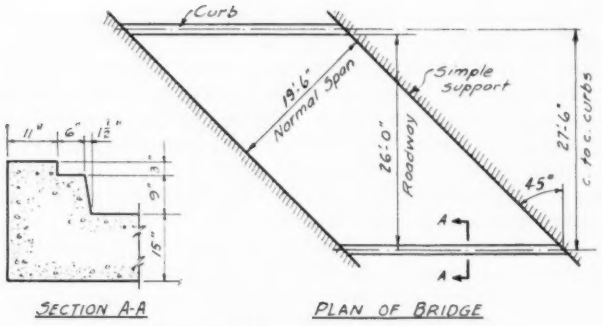

FIG. 1 SKEW-SLAB-BRIDGE DETAILS

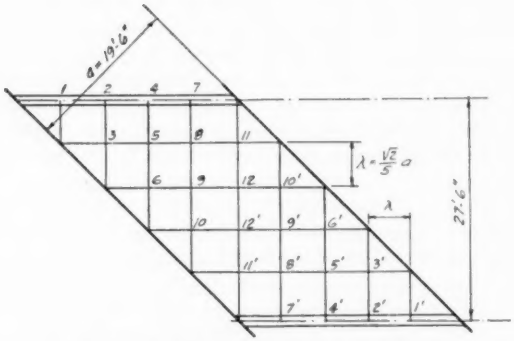

FIG. 2 NETWORK FOR ANALYSIS

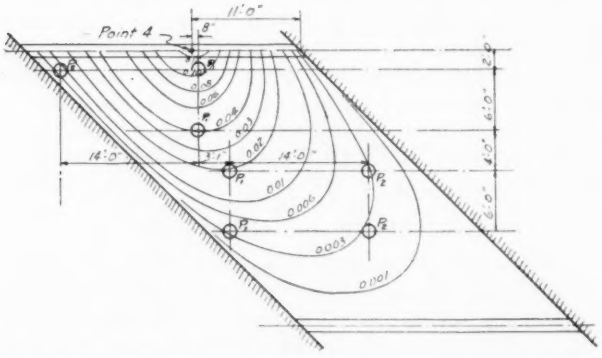

FIG. 3 INFLUENCE SURFACE FOR MOMENT IN CURB AT POINT 4

wherein EI designates the "stiffness" of the curb, λ is the distance between successive points of the network, and w designates deflection. By Newmark's theorem the influence surface for moment at point 4 will, therefore, be given by the deflection of the slab due to loads

$$P_4 = \frac{2EI}{\lambda^2} \qquad P_2 = P_7 = -\frac{EI}{\lambda^2}$$

Determination of the deflection of the slab loaded in this manner yields an influence ordinate at each point of the network.[3] Contours of the influence surface having these ordinates are shown in Fig. 3.

With the influence surface known, it becomes possible to determine the effect of truck-wheel loads for various positions on the lanes of traffic. Because the distances of the traffic lanes from the curb are specified, it is a simple matter to determine graphically the maximum moment in the curb due to each set of truck-wheel loads. The final position of the loads for maximum moment in the curb is shown in Fig. 3, when the rear-wheel loads P_1 are 4 times as great as the front-wheel loads P_2.

The Effect of Foundation Stiffness on the Resonant Frequencies of Rotating Machines[1]

T. C. RATHBONE.[2] The status of the vibration problem as affected by foundations is still far from satisfactory, hence this paper, describing a somewhat different method of attack, is a most welcome contribution. It is evident from the author's results that a great amount of valuable information can be obtained readily and simply by means of nonrotating prototypes.

In addition to those mentioned in the paper, some practical observations occur to the writer, which are offered as supplementary to the text, having to do principally with disparities of a secondary nature between the nonrotating model and the actual installation.

The transit of nodes in the "rotor" across the "bearings" with varying speeds, as so well illustrated in the diagrams, has amply been borne out by actual experience on large installations. No better exposure of the futility of attempting field balancing by the "horse-and-buggy" method of scribing the shaft to locate the balance correction could be asked for. Obviously, the scribed "high spot" will practically reverse itself as the node passes from one side of the scribed location (usually between the bearing and the gland or end-bell) to the other, with no change in the initial unbalance. Quite recently, the writer was assured that a turbine, still obviously vibrating badly, had been satisfactorily balanced, because the scribed mark showed all around the shaft! A node probably occurred at the scribed location.

Phase relationships have an additional meaning with the rotor actually rotating. Directional characteristics are absent with the linearly vibrating nonrotating member; the point on the generating circle for the harmonic motion in the vertical plane can be considered as rotating in either direction, while on the actual machine, the exciting forces together with the indexes are rotating in a fixed direction. On large units, the vibration characteristics can exhibit considerable differences between clockwise and counterclockwise rotation. This sounds paradoxical, but is inherently true.

The difference is brought about by the intercommunication of vibratory disturbances from one bearing to another through the foundation and stationary parts and by the time lag which depends upon the velocity of sound (impulse transmission) through the structure, during which lag the high-speed rotor can turn through a considerable angle. For example, with a modern, large 3600-rpm unit, having a distance of, say, 45 ft between the No. 1 and the outboard bearing, the rotor will turn through about 60 deg before a disturbance emanating from one bearing reaches the other. As the vibration at each bearing is a composite of the disturbances coming from the entire unit, the vector additions will give different resultants for the two directions of rotation. By the same token, if the assumed concentrated unbalance at one end of the rotor leads that of the other end by 90 deg, the vibration of the unit will not be the same as when it lags 90 deg.[3]

Another seeming paradox appears when exploring the relation between the phase of the bearing vibration, as referred to a datum on the rotor, and the speed. On actual tests on a large rotor, contrary to the expected shift from zero to 180 deg, the angle changed through over 700 deg, nearly two complete rota-

tions, between rest and about 1900 rpm, and at a fairly uniform rate. This observation was made on the bearing, not on the shaft. Parallel data obtained on the shaft would furnish the relative motion between bearing and shaft by vectorial subtraction.[4]

The influence of the mat and ambient soil may introduce another variant from the prototype that may warrant recognition. Professor Bernhard has shown the effect of the vibrating mass of soil on the over-all dynamic characteristics of the installation.[5] Earth vibration from 1800-rpm turbines at a distance of several hundred feet has been observed and measured. In such cases, the mass and elasticity of the probably damp soil might have considerable influence. K. H. Larkin[6] gives data on the natural frequencies of soils in connection with Diesel-engine foundations, which indicate that the frequency increases as the unit loading decreases, and proposes that resonances with engine impulses can be avoided by selecting appropriate bearing area for the base.

Even though the nonrotating prototypes cannot duplicate all the full-size rotating characteristics, the informative data already obtained by the author in such a simple and inexpensive manner warrants extending this work to embrace a third system, representing the mat and its elastic support, and also the two-rotor three-bearing system with solid coupling.

H. D. Taylor.[7] This paper should be of special interest to all persons concerned with the mechanical operation of high-speed machinery, particularly turbine-generators. It indicates definitely that resonant speeds, at which unbalances may produce peaks of vibration, depend quite as much upon foundation stiffness as upon the conventional critical speeds of the rotor, calculated on the usual tacit assumption of rigid support at the bearings. A uniform shaft has the familiar series of critical speeds, for 1-, 2-, 3-, and 4-loop forms of vibration, in the ratio of 1, 4, 9, 16, as closely approximated in the tests reported in the paper, and shown in Figs. 4 and 5. A turbine-generator-type rotor, however, indicates relative speeds of about 1.0, 2.9, 6.4, 8.7, as illustrated in Fig. 16. The difference is due to the stepped diameters of the generator-type rotor, as shown in Fig. 14 of the paper. This type of rotor, assembled with its heavy stator, and mounted on a foundation of appreciable flexibility (i.e., any practical foundation for a large machine), will have all of its "criticals" depressed appreciably, the higher orders probably more, relatively, than the lower ones, as shown in Fig. 15 of the paper. In the examples tabulated by the author, the resonant speeds may be expressed as ratios based upon the fundamental critical speed of 2400, as follows:

Form	Rigid foundation	Elastic foundation — Vertical	Elastic foundation — Horizontal
1 loop	1.00	0.634	0.208
2 loops	2.94	1.087	0.337
3 loops	6.41	1.117	1.063
4 loops	8.74	3.00	3.00

In Figs. 15 and 16 of the paper, it is not quite clear that series B is derived from the basic form 3; that is, curve B approaches and merges with form 3 as the foundation stiffness is increased. Likewise, series D is derived from basic form 4. These relationships were shown in Fig. 7, as an extrapolation of the observations on a uniform shaft, but they apply definitely to the generator-type rotor also. They may be shown in another manner, perhaps more readily grasped, by plotting the test curves against foundation flexibility rather than stiffness. This permits the curves to start with zero flexibility which, of course, cannot be included in the present diagrams because it corresponds to infinite stiffness. The curves, in effect, would be reversed. The depression of all the criticals with increasing flexibility of the foundation can be shown clearly, starting from the familiar values as calculated for a rigid foundation.

The information given in this paper should be of material value in the development of the technique of refining the balance of turbine-generators and other high-speed machinery. In this connection, however, the writer would like to propose an amendment to the author's statement that "in most actual systems, all forms of resonance are excited by a single force, irrespective of position." This does apply to the type of laboratory test setup employed, having very little damping and being therefore very sensitive to properly tuned frequencies. However in work with rotating equipment, it has been the writer's experience that the arrangement or distribution of unbalances has a major effect on the roughness encountered at the various resonant speeds. "Static" unbalance brings out primarily the fundamental 1-loop form, and also in many cases the 3-loop form, but not the 2-loop or 4-loop forms; whereas, "dynamic unbalance," or a "couple," produces 2-loop or 4-loop vibration, but not the 1-loop or 3-loop varieties. These statements are based upon work with rotors which are symmetrical along their length, and may not hold for seriously unsymmetrical cases.

Referring again to Fig. 15, curve D indicates a resonance at 7200 vibrations per min which speed was almost constant, for the particular combination of rotor and stator, over a wide range of foundation stiffness. It might be expected that, if an actual 3600-rpm generator were built to the same proportions, it would be likely to get into trouble from the twice-per-revolution gravity deflection of the rotor. However, the gravity deflection is essentially a 1-loop phenomenon, like static unbalance, except for the double frequency; and the form of vibration required for this 7200-vibrations-per-min resonance is a 2-loop pattern (as shown at point 18 of Fig. 16) which should be responsive only to "dynamic" or couple-type stimulation. Therefore, it seems to the writer that this disturbance would not ordinarily appear. Such trouble might be encountered, however, if the rotor-deflection curve happened to be considerably unsymmetrical along its length, or if the machine proportions were such that either the 1-loop or 3-loop type of resonance, shown as series B and E in Fig. 15 (actually depressed 3-loop and 5-loop criticals), should happen to come at 7200 vibrations per minute.

The existence of a large number of resonant speeds or depressed "criticals," within the running range of high-speed turbine-generators has been perhaps not generally recognized, and might be viewed with some alarm. There should be no great concern about this, however, as it is common experience that refined balancing by modern methods takes care of them. In general, balancing work can be expedited if the resonant characteristics of the setup are understood. Here, it is believed, the author has made a significant contribution to the art.

Author's Closure

The author is indebted to Mr. Rathbone for adding his observations on full-scale machines, which confirm and enlarge the model data. There are of course many effects due to rotation which cannot be shown with a nonrotating model.

When we can work again on this project, there are several phases which can be studied by means of nonrotating models, such as, foundation mats and three-bearing sets, as suggested by Mr. Rathbone, as well as the effect of elastically supported stators in two-pole generators, on which some model work has already been done.

Mr. Taylor has contributed several valuable ideas in his discussion, in addition to those made previously during the course of this work.

As Mr. Taylor indicates, series B has not taken on form 3 within the stiffness range of these experiments. As the foundation becomes more rigid, series B approaches form 3 by bringing the two nodes inside the bearings closer together. At the same time, a node appears outside each bearing, which progresses inward, arriving at the bearings when the foundation is rigid, giving form 3. The latter behavior is seen in series C.

It would be instructive to plot these model data as a function of flexibility rather than stiffness. Stiffness was used from selfish motives, the author having visualized the phenomena in that way.

Book Reviews

Mechanics Applied to Vibrations and Balancing

MECHANICS APPLIED TO VIBRATIONS AND BALANCING. By D. Laugharne Thornton. John Wiley & Sons, Inc., New York, N. Y., 1940. Cloth, 9¾ × 6 in., xii and 529 pp., 180 figs., $7.50.

REVIEWED BY J. ORMONDROYD[1]

BOOKS on mechanical vibrations have become numerous enough so that a newcomer in the field is eyed very critically. The content of this book and its treatment differ sufficiently from the content and treatment in other books on the same subject to justify its appearance.

The book gives an account of vibration theory and its applications which would appear to be practical to a mathematical physicist. It probably will seem rather mathematical and "theoretical" to the practicing engineer. The mathematics used is, of course, no more difficult or abstruse than that which must necessarily appear in any good work on the subject—but the physical introduction to the equations is curt and abbreviated—after the fashion of publishing physicists who assume they are speaking to their peers. To one already skilled in the art of vibration analysis, the work will be useful and stimulating. To a novice in the field it will not be so helpful. The very points over which the struggling engineer would stumble and hesitate are passed over by the author with a mere wave of the hand and the inevitable "it can readily be seen." Although the book is learned, it is not systematic enough in treatment and, in many respects, it is too superficial to be used by an engineer who lacks extensive training or interest in physics and mathematics.

To those who have already struggled successfully through the fundamental, elementary aspects of the subject the book has much to offer. Although practically all the problems treated can be found scattered through many existing treatises and papers, the combination put together by the author is somewhat unique. Chapters 1 and 2 give a more complete graphical and analytical treatment of reciprocating engine balancing than can usually be found in one place. Chapter 4 on the propagation of stress in elastic materials gathers together material which is of extreme practical interest to engineers today. Impactive or explosive loadings in metals, concrete, fluids, and air are coming more and more to the attention of design engineers. This chapter gives the concepts and procedures necessary for intelligent treatment of problems of this nature. Chapter 6 on rotating shafts and disks goes into the dynamics of these widely used elements of machinery more fundamentally and extensively than most treatments of this subject. Chapter 3 on the theory of vibrations besides giving the usual elementary and more sophisticated development of the subject contains three interesting sections on the vibrations of structural frames and buildings—a subject too much neglected by civil engineers, considering its practical importance.

The author illustrates the application of all the theory treated by means of numerous worked examples of a practical nature. In these examples he shows a knowledge of real problems in widely diversified fields. The book is primarily a practical treatise written from the outlook and background of a mathematical physicist. If the treatment causes bewilderment to the engineer, it is to be charged against his academic training and interests rather than against the author. Present-day trends in purely technical fields are such that physicists with mathematical training may soon displace engineers with the usual training in all the fields where really interesting and important developments are taking place. "Statics" has become the humble servant—"dynamics" has mounted the throne.

"Mechanics Applied to Vibrations and Balancing" is a book which has significance because of this fact.

Kinetic Theory of Gases

AN INTRODUCTION TO THE KINETIC THEORY OF GASES. By Sir James Jeans. Cambridge University Press, London, England; The Macmillan Company, New York, N. Y., 1940. Cloth, 5½ × 8½ in., 311 pages, $3.50.

REVIEWED BY JOSEPH HENRY KEENAN[2]

IN his preface the author sets forth his purpose as follows: "I have intended that the present book shall provide such knowledge of the Kinetic Theory as is required by the average serious student of physics and physical chemistry. . . . . the book covers a good deal of the same ground as my earlier book, 'The Dynamical Theory of Gases' but it is covered in a simpler and more physical manner. Primarily, I have kept before me the physicist's need for clearness and directness of treatment rather than the mathematician's need for rigorous general proofs."

When one reads a classic work of rigor like "The Dynamical Theory of Gases," one is inclined to speculate whether the author ever thinks in terms of examples that are concrete, though crude, and graphic, though approximate. Here is evidence that at least one such author can match the most pictorial-minded in the explanation of complex concepts.

Any engineer with a little analytical experience will be able to follow most of the arguments. In the earlier chapters the reader finds himself taken by the hand and led by slow steps to those slight eminences from which some of the vistas of Kinetic Theory begin to unfold. Later the going becomes heavier, but nothing in this little book of 300 pages should be too formidable to one versed in mechanics.

There is frequent reference to thermodynamics in these pages, but there is no exposition of the principles of thermodynamics.

[2] Professor of Mechanical Engineering, Massachusetts Institute of Technology, Cambridge, Mass. Mem. A.S.M.E.

On at least one occasion the thermodynamic treatment is inadequate. The reader should bring his own thermodynamics and not expect to find it provided for him.

There are simple and readable explanations of the experimental verification of Maxwell's Law of Distribution, of the reasons why viscosity is independent of density (and when it is not), of Brownian movements, the relation between electrical and thermal conductivity, the distinction between liquid and vapor phases, and many other things.

It is not popular science; it is good science in a form that should appeal to the engineer.

Relaxation Methods in Engineering Science

RELAXATION METHODS IN ENGINEERING SCIENCE—A Treatise on Approximate Compution. By R. V. Southwell. Oxford University Press, New York, N. Y., 1940. Cloth 6 × 9½ in., vi plus 252 pp., $6.

REVIEWED BY HARDY CROSS[3]

THE author of this book, who is professor of engineering science at Oxford, has brought together work done during the last five years by himself and others in England. Of the twelve chapters, four deal with stress analysis in frames, five with vibrations and buckling, the others with miscellaneous problems including flow in distribution systems and adjustment of errors in surveys. The methods used are those of successive approximation, which are here called "relaxation methods."

For more than a decade there has been much interest in this country in methods of successive approximation—"methods of convergence," "iteration," "distribution procedures." Some books, various papers, and many important unpublished theses, memoranda, and lectures have treated the problems included in this book and have extended the study to other problems not here treated. Much of this American work has apparently not come to the attention of the author.

The term "relaxation" originates from the physical concept of step-by-step relief of artificial restraints imagined for purposes of analysis to restrict deformation of structural frames; general use of the term does not, however, seem especially apt. Various specialized terms appear throughout the book—"liquidation" of restraints, "block relaxation," "unit problem," "gyrostatic systems." The author brushes aside much terminology, methodology, and symbolism that has obscured the palm in "classical" mechanics. Scholarly chariots usually stir up a good deal of dust on the road to knowledge; by comparison, the author's material is relatively unclouded by complications. Most of the solutions are, as the title indicates, those of "engineering science" rather than of engineering, so far as this distinction has validity. Thus in continuous frames, the problem, as here treated, is to find the stresses rather than to discuss the dependability or importance of these as elements in stability.

The subtitle of the book seems somewhat misleading; this is not a general treatise on methods of successive approximation nor should methods of successive approximation be confused with approximate methods. American students will find interest in this contribution to what the author calls the "new mathematics," which makes it easier for the engineer to "take account of the unavoidable uncertainty of physical data." Methods of successive approximation are not "new," but methods of direct solution without symbolism are very powerful for the engineer, as this scholar explains.

Strength of Materials

STRENGTH OF MATERIALS. By S. Timoshenko. Second Edition. D. Van Nostrand Company, Inc., New York, N. Y., 1941. Cloth, 6 × 9 in., Part I. Elementary Theory and Problems. vii and 359 pp., figs., $4.50. Part II. Advanced Theory and Problems, xiii and 510 pp., figs., $4.50.

REVIEWED BY C. RICHARD SODERBERG[4]

THE appearance of a new edition of the two volumes of "Strength of Materials" by Professor Timoshenko is welcomed warmly by many engineers and teachers, who have become accustomed to look to this treatise for the solution of many important strength problems.

Although the scope of the new edition follows very closely that of the first, which appeared 11 years ago, there have been many changes, all of them enhancing the utility of the volumes for teaching purposes. The first volume has been rearranged to include less material of an advanced nature, which has in turn permitted the expansion of certain chapters. Chapter 2, covering the analysis of stress and strain, has been rewritten, and chapter 8, covering combined bending and tension, now contains a valuable introductory discussion of column theory.

In the second volume the principal changes occur in chapters 3, 8, and 9. Chapter 3 presents a treatment of thin plates and shells, which within the limited space allotted succeeds in giving a remarkably complete discussion of this important subject. Chapter 7, covering deformations beyond the elastic limit, gives a much more extensive treatment of this subject than that of the first edition. Chapter 9, on mechanical properties of materials, is much expanded, giving a considerable amount of an experimental nature which has become available since the publication of the first edition. Both volumes contain a large number of problems and practical applications which bear testimony to the author's wide experience.

The new edition has lost nothing of Professor Timoshenko's lucid style and clear reasoning, so familiar to those of us who have had the privilege of working with him. It seems presumptuous to advance even minor criticisms to a work of such outstanding merit, but certain aspects of the first edition which have not been fully corrected in the second edition seem worthy of note.

The analysis of stress and strain at a point, while adequate for the first volume, seems too brief and sketchy for much of the material of the second volume. This is certainly true when the book is used as reference in a more advanced course on strength of materials. The tensor nature of stress and strain is a fact worthy of attention, at least to those who expect to follow the studies of the subject into the more general theory of elasticity. A modest expansion of this point would also serve to lay a firmer basis for the subsequent treatment of yielding, particularly with reference to creep. The conventions which serve as a basis for Mohr's circle are not much clearer than those of the first edition, which in the past has been one of the objections to this part of the book.

The considerable extent to which the strain-energy method is used in the second volume would seem to justify a fuller treatment of the foundation upon which the basic theorems are based than that presented in chapter 10 of the first volume. The conventional proof of the theorem of Castigliano is not convincing, and usually leads to a stereotyped form of application which obscures the real possibilities of the strain-energy method. In fairness it should be conceded, however, that very few treatises do more with this subject than what is presented here.

While chapters 8 and 9 of the second volume, on deformations

[4] Professor of Applied Mechanics, Massachusetts Institute of Technology, Cambridge, Mass. Mem. A.S.M.E.

beyond the elastic limit and mechanical properties of materials, give an excellent summary of the subject, its treatment of plastic flow and creep could justify some extension. In the modern power industry creep plays a very important role, and a great deal of confusion exists with regard to the possibility of predicting flow under two- or three-dimensional stress from the information obtained through tensile tests. A book of this kind could perform a very useful service in clarifying these phenomena, on which a great deal of information is now available. Creep of boiler tubes, as an example, seems to the reviewer to be a far more important subject than the results which are presented for plastic deformations above the yield strength at room temperature.

The reviewer hastens to add that these points, some of which may be regarded as matters of taste, do not detract from the outstanding merit of "Strength of Materials." It will continue to remain a standard reference and textbook for a long time to come.

Statistical Mechanics

STATISTICAL MECHANICS. By Joseph Edward Mayer and Maria Goeppert Mayer. John Wiley & Sons, Inc., 1940. Cloth, 6 × 9¼ in., xi and 495 pp., illustrations, $5.50.

REVIEWED BY JOHN A. GOFF[5]

As van der Waals so clearly pointed out, the laws of thermodynamics themselves lead only to a series of identical relations between mechanical properties such as pressure, volume, temperature, and composition on the one hand, and calorimetric properties such as internal energy, entropy, and so on, on the other. The very fact that these relations enjoy the most general validity means that they are incapable of giving specific information regarding any particular substance. Hence it is absolutely necessary to implement the laws of thermodynamics in some way or other if they are to be given practical usefulness.

The perfect gas laws represent the earliest implementation of the laws of thermodynamics. While these laws were suggested by the experimental findings of Boyle, Charles, Gay-Lussac, and Regnault, nevertheless, subsequent more refined measurements have shown them to be strictly applicable to no known substance. They must, therefore, be regarded as purely hypothetical however useful they may be as such. In the development of our present accurate and comprehensive body of knowledge regarding the thermodynamic properties of water, all temptations to hypothesize were scrupulously avoided and direct experimental data insisted upon. But even in steam research, it soon appeared that the accuracy of and confidence in the final formulation could be greatly enhanced by utilizing the predictions of modern statistical mechanics based upon quantum mechanical interpretation of the spectrum of the water molecule.

Thus, within comparatively recent times, the science of statistical mechanics has been developed into a powerful method of implementing thermodynamics. For example, its quantitative predictions regarding the zero-pressure properties of gases are now generally regarded as more accurate and trustworthy than values inferred from direct calorimetric measurements. Moreover, its qualitative predictions form an invaluable guide to thermodynamic research and have greatly enhanced our understanding of the fundamental concepts of thermodynamics and their limitations. The result has been to make of what was formerly regarded as the plaything of the physicist an effective tool for the engineer. Obviously, therefore, it has become important for the engineer to comprehend the fundamentals of statistical mechanics in order that he may judge for himself the accuracy of its predictions. The present book must be regarded as one of the most significant aids toward this comprehension which has yet appeared.

The aim of the book, according to the authors, is to present the subject in as simple a manner as possible without sacrifice of rigor. Care has been taken to make the book suitable for reference by summarizing and tabulating final equations and making individual chapters complete in themselves. Written primarily for graduate students in physics, its scope and practical treatment will appeal to the engineer also.

The first chapter gives an illustration of the possibility of statistical methods by reviewing its application to the perfect monatomic gas in which the only mode of motion is that of translation. The concept of mean free path is introduced and its use in the treatment of transport phenomena, viscosity, heat conduction, and diffusion is briefly sketched. No fundamental assumptions except the validity of the laws of mechanics are introduced.

Chapter 2 is entitled, "Mechanical and Quantum-Mechanical Preliminaries." It describes the use of generalized co-ordinates in terms of which the Heisenberg Uncertainty Principle, the concept of quantum states, and the law of equal probability of single states find their most general expressions. The differential equation defining the wave function is written down and, by application to such simple systems as a point particle moving in field-free space, the harmonic oscillator, and the symmetrical top, it is shown how this function predicts discrete energy levels. Perhaps an important defect of this chapter is its failure to emphasize the postulatory character of the wave equation. The prediction of discrete energy levels is so startling to a reader not too easily converted from the classical point of view that he must leave the chapter with a feeling of skepticism.

In chapter 4 are derived the laws of thermodynamics with a discussion of their limits of validity. Special interest attaches to the discussion of the so-called Third Law of thermodynamics. It is pointed out that the general statement of the law has no great value to the experimental thermodynamist; for, though it is highly probable that it is true, nevertheless so many anomalies may occur in the range of inaccessibly low temperatures that no general directions for its application in purely experimental terms can be given. Still, confirmation of the law has been indicated in many cases where such anomalies either do not occur or can be delineated by the expert in quantum mechanics. Hence, the value of the law in illuminating the region of very low temperatures and thereby clearing away many misconceptions of classical thermodynamics must not be underestimated.

In subsequent chapters, it is shown how the equations for the energy levels of monatomic, diatomic, and polyatomic perfect gases can be used in interpreting spectra to obtain the necessary data for the calculation of thermodynamic properties of actual gases at zero-pressure. In chapter 13 is given an account of present progress toward predictions of the properties at finite pressures where an analysis of the effect of intermolecular forces must be made. No account seems to be given of the theory of gas mixtures, a subject of increasing practical importance in which confusion is rife and the need for help from statistical mechanics is especially urgent.

Space, and other obvious considerations, will not permit enumeration of all of the applications treated; suffice it to say that the book gives remarkably wide coverage. It is believed that the book will find favor with the physicist who has need of a reliable reference to aid in making practical use of the theory and with the engineer who wishes an insight into the fundamental theory and some comprehension of the nature and scope of its predictions.

von Kármán Anniversary Volume

THEODORE VON KÁRMÁN ANNIVERSARY VOLUME. Contribution to Applied Mechanics and Related Subjects. By the Friends of Theodore von Kármán on His Sixtieth Birthday. California Institute of Technology, Pasadena, Calif., May 11, 1941, 8½ × 11 in., xv and 337 pp., $3.75.

REVIEWED BY ALBERT E. HEINS[6]

ON the sixtieth birthday of Theodore von Kármán, twenty-three scholars in the United States and Canada, who are former pupils or friends of his, have dedicated an anniversary volume to him. Because of the present world crisis, scholars abroad have been prevented from contributing to this volume. The name von Kármán needs no introduction to the engineer, applied mathematician, or physicist. Clark Millikan, the editor of this volume, has summed up adequately in the foreword the many accomplishments of von Kármán in the fields of elasticity, hydrodynamics, aerodynamics, and applied mathematics. The central theme of this volume is mechanics, and it is particularly appropriate since von Kármán has made so many fundamental contributions to the various phases of mechanics. In addition to the twenty-three scientific papers, there is a short biography of Theodore von Kármán and a bibliography of his papers. From the table of contents:

H. Bateman: "Some Definite Integrals in Aerodynamics"
Max M. Munk: "On the Geometry of Streamlining"
J. C. Hunsaker: "Dimensional Analysis and Similitude in Mechanics"
Th. Thedorsen: "Impulse and Momentum in an Infinite Fluid"
Boris Bakhmeteff: "Coriolis and the Energy Principle in Hydraulics"
H. U. Sverdrup: "The Influence of Bottom Topography on Ocean Currents"
W. F. Durand: "Ionization as a Factor in Fluid Mechanics"
Hugh L. Dryden: "Isotropic Turbulence in Theory and Experiment"
J. L. Synge and W. Z. Chien: "The Intrinsic Theory of Elastic Shells and Plates"
Francis D. Murnaghan: "The Compressibility of Solids Under Extreme Pressures"
F. Zwicky: "Hydrodynamics and Structure of Stellar System"
H. M. Westergaard: "On the Elastic Distortion of a Cylindrical Hole by a Localized Hydrostatic Pressure"
Paul S. Epstein: "On the Absorption of Sound Waves in Suspensions and Emulsions"
R. Courant: "Method for Solution of Boundary Value Problems"
Karl Arnstein: "Engineering Treatment of Ring or Wheel Problems"
A. Einstein, V. Bragmann, and P. G. Bergmann: "On the Five Dimensional Representation of Gravitation and Electricity"
S. Timoshenko: "The Forced Vibrations of Tie Rods"
Th. Troller: "Effect of Wind-Tunnel Size on Pitching-Moments"
A. Nádai: "Creep of Metals Under Various Stress Conditions"
K. O. Friedrichs: "Minimum Buckling Load for Spherical Shells"

Theory of Plates and Shells

THEORY OF PLATES AND SHELLS. By S. Timoshenko. Engineering Societies Monographs. First Edition, McGraw-Hill Book Company, Inc., New York, N. Y., 1940. Cloth, 6 × 9 in., xii and 492 pp., 189 figs.

REVIEWED BY A. NÁDAI[7]

THIS book is concerned with the discussion of the distortion of elastic bodies in which one dimension is small compared with the other dimensions. Problems concerning disk-shaped plane bodies stressed in their middle plane are excluded. Three hundred fifty pages are devoted to the bending theory of thin plates and one hundred thirty-two pages to the deformation of curved shells. The content of the first chapter carrying the title "the bending of long rectangular plates to a cylindrical surface" may be summarized by stating that it essentially still belongs to the elementary bending theory of slender bars under a lateral and axial load. The second chapter entitled "pure bending" contains the formulas for the slopes, curvatures, and bending moments of uniformly bent plates for different directions; the third chapter, the bending of circular plates having a rotational symmetric distortion; the fourth "small deflections of laterally loaded plates" including a discussion of the boundary conditions for plates. The following four boundary conditions are considered: the built-in, the simply supported, the free edge, and the elastically supported edge. Using rectangular coordinates x, y the simply supported edge is defined as follows: "if the edge $y = 0$ of the plate is simply supported the deflection w along this edge must be zero. At the same time this edge can rotate freely with respect to the axis, i.e., there are no bending moments M_y along this edge." The two conditions are given as

$$y = 0, \quad w = 0, \quad \frac{\partial^2 w}{\partial y^2} + \nu \frac{\partial^2 w}{\partial x^2} = 0$$

(ν Poissons ratio). If the condition $w = 0$ is essential for a simply supported edge, and since a straight edge is assumed, in the expression for the second boundary condition the term $\partial^2 w/\partial x^2 = 0$ and this condition should have been written simpler as $\partial^2 w/\partial y^2 = 0$. This "simply supported edge" is illustrated in Fig. 49, p. 89, showing a wedge-shaped edge hinged in a corresponding obtuse angle. For a plate carrying a *lateral* load such a support could not well be used. It seems that more justice could have been done to the practical sense of the reader (and to those who have previously discussed the same case) by admitting that what in textbooks including the present one has generally been considered to represent the conditions of a freely supported plate edge is a mathematical definition. When the author on the other hand introduces the expression $\frac{\partial^2 w}{\partial y^2} + \nu \frac{\partial^2 w}{\partial x^2} = 0$ despite the fact that each of the two terms in it are to be taken equal to zero, he had in mind that this was one of the two necessary conditions to be satisified for a simply or freely supported plate edge, with which the reviewer agrees. The trouble comes from the preceding condition and an unwarranted assumption that along a simply supported edge the deflection of the plate "must be zero." The experiments of C. Bach and of M. Bergstraesser have shown that a rectangular plate carrying transversal forces (weight) can rest freely on a smooth rigid edge situated in a plane but the deflections will be zero only in certain points along the edge. What makes the integration of the plate equation $\Delta \Delta w = f(x, y)$ possible using trigonometric and hyperbolic functions is really the fact that the conditions $w = 0$ and $\partial^2 w/\partial x^2 = 0$ or $\partial^2 w/\partial y^2 = 0$, respectively, for a rectangular plate are a special case of the two bound-

[7] Consulting Mechanical Engineer, Westinghouse Research Laboratories, East Pittsburgh, Pa. Mem. A.S.M.E.

ary conditions $w = 0$ and $\Delta w = \partial^2 w/\partial x^2 + \partial^2 w/\partial y^2 = 0$ which permit a double periodical development of the elastic surfaces w and Δw with an analytical continuation around the four corners of the plate. (The reviewer called them the boundary conditions of Navier.) If the student of the plate theory uses them with advantage, he should be aware that they are of a mathematic nature and that he should satisfy himself with a futher investigation of what happens also to the transversal shearing forces along the edges of the plate.

When reading paragraph 25 which is entitled "exact theory of plates" readers will conclude that the theory of the plate equation $\Delta\Delta w = f(x, y)$ to which the preceding and most of the following chapters of the book are devoted is less exact. This distinction between a "rigorous" and a less exact theory of plates which is also to be found in Love's treatise is somewhat misleading. It is shown when $\Delta w = \text{const}$, i.e., the shearing forces vanish or the stresses $\tau_{xz} = \tau_{yz} = 0$ that both theories (the Kirchhoff and the rigorous theory) are really identical. Now if Δw is not a constant or zero the case is essentially not much different as long as one of the fundamental assumptions on which the Kirchhoff theory rests has not been given up, namely, that h/a (h plate thickness and a a dimension in the plate) remains small. The second or correction terms in Equation (s), p. 111, referring to the exact theory are insignificant since the terms containing z have a factor h^2 and those of order z^3 are negligible compared to z. There is only one apparent exception to the rule. It refers to the formulas for the maximum stresses for plates under a concentrated force. When a singularity in the solution of a differential equation occurs of such a nature that one or more of the derivatives become infinite, for which the solutions are established, the corresponding expressions fail. This is not a weakness of the theory, but a consequence of a mathematic abstraction (concentration of a force in a mathematic point) which must then be modified.[8]

After the introductory chapters a large number of special cases are reported in detail such as rectangular plates with various end conditions, plates with various shapes, stretched and bent plates, and those with large deflections. The last three chapters of the book deal with the deformation of shells without and with bending including the theory of cylindrical and spherical shells.

Photoelasticity

PHOTOELASTICITY. By Max Mark Frocht. Vol. 1. John Wiley & Sons, Inc., New York, N. Y., 1941. Cloth, 6 × 9 in., xi and 401 pp., illustrated, $6.

REVIEWED BY W. M. MURRAY[9]

THIS book is a welcome addition to the available literature on photoelasticity. It brings together in one volume the fundamentals of the photoelastic method of stress analysis and the results of the investigations of an outstanding authority in the field. In volume one the author has confined his attention to the basic theory of photoelasticity and the interpretation of the information which can be obtained from observations with the polariscope. This is supplemented with information on the laboratory technique of the method.

In the initial chapter a rather comprehensive review of two-dimensional stress and strain with their respective relations is taken up even to the point of including information on strain rosettes.

A chapter is devoted to the development of the equations of equilibrium for plane stress in Cartesian, polar, and curvilinear co-ordinates. The equations are developed both in terms of the stress trajectories and the lines of maximum shear stress.

The nature of light and a consideration of elementary optics are taken up in two chapters. In this section are included such topics as reflection, refraction, simple harmonic motion, wave theory, polarization, and double refraction. Space is devoted to items such as dispersion, color, interference, intensity of illumination, and the mechanism of operation of different arrangements for polariscopes.

The actual interpretation of the photoelastic phenomena is commenced in the fifth chapter where various methods of calibration of material and determination of the difference between the principal stresses are taken up in detail. This is followed by a chapter dealing with the determination of the isoclinic lines and stress trajectories from observations with the polariscope. This is rather complete and includes information dealing with various kinds of isotropic points and the layout of the trajectories in their locations.

The following three chapters are devoted to the separation of the principal stresses within the model or the determination of the normal and shearing stress components across a given section. Several examples are solved using the slope-equilibrium method for sections of symmetry, the shear-difference method for arithmetic integration along an arbitrarily chosen straight line, and the graphical-integration method of Filon for working into the interior of the model along a stress trajectory.

A very welcome departure from most other texts on this subject is to be found in the last two chapters where the author gives a discussion of photoelastic materials and their properties. This is supplemented with useful comments on the preparation of the models and the actual laboratory and photographic technique. Some space is devoted to the general features of photoelastic equipment including polariscopes, testing machines, cameras, and light sources.

The book contains a great many diagrams to illustrate the text and a large number of photographs of stress patterns. The latter deserve special mention, as many of them are used in numerical examples which are worked out in detail to show the various methods of interpreting the laboratory observations. Although this work is not nearly so comprehensive as the "Treatise on Photoelasticity" by Coker and Filon, to whom it is dedicated, it provides sufficient material to be somewhat more than an engineers' manual and, at the same time, it retains the simplicity which makes it a suitable text for students of senior or graduate grade. To this end the author has included a number of problems and exercises which should be of considerable assistance for classroom use. The first volume does not contain a discussion of the auxiliary methods of analysis which have helped to make photoelasticity such a convenient engineering tool and it is hoped that these will be included in the second volume.

Volume one is a monument to the personal investigations of the author and the laboratory technique which he has successfully developed. The numerical checks which he has obtained from his calculations will do much to dispel, from minds of the skeptical, the idea that photoelasticity is only a qualitative tool. To the publishers must be given credit for the splendid presentation and printing of the book which contains so many illustrations a few of which are in color.

[8] It must by the way be questioned in some applications whether one is better off by taking resource to the formulas of the exact theory if the ratio a/h becomes too small, say, for example $h/a = 0.6$ (a case which is quoted in the book on p. 78 showing in Fig. 44 the corrected deflection line for a "thick" circular plate for a center load). The nearness of those portions along the periphery of the plate in which the reactions are transmitted to the central portion upsets the assumptions of the exact theory about the distribution of the transversal shearing stresses.

[9] Assistant Professor of Mechanical Engineering, Massachusetts Institute of Technology.

Steady Flow in the Transition Length of a Straight Tube[1]

By HENRY L. LANGHAAR,[2] LAFAYETTE, IND.

By means of a linearizing approximation, the Navier-Stokes equations are solved for the case of steady flow in the transition length of a straight tube. The family of velocity profiles is defined by Bessel functions, and the parameter of this family is tabulated against the axial co-ordinate in a dimensionless form. Hence, the length of transition is obtained. The curves give a comparison of the author's calculations of the velocity field with those of other investigators,[3,4,5] and with the experimental data of Nikuradse.[6] The pressure function is derived from the computed velocity field by means of the energy equation, and the pressure drop in the transition length is defined by a dimensionless constant *m*, which is computed to be 2.28. A discussion of this constant is given in the conclusions.

Notation

x, y, z = rectangular coordinates of a point. The center line of the tube is on the z axis, with the inlet at $z = 0$

r, θ, z = cylindrical co-ordinates of the point x, y, z

ω = cross-sectional area of the tube

a = radius of the tube

$q = r/a$ = dimensionless radial co-ordinate

u, v, w = x, y, z components of the velocity field

w_0 = velocity on the center line of the tube

c = mean velocity in the tube

$\lambda = w/c$ = dimensionless axial velocity

$\lambda_0 = w_0/c$ = dimensionless velocity on the center line of the tube

ρ = mass-density of the liquid

ν = kinematic coefficient of viscosity

$\mu = \rho\nu$ coefficient of viscosity

$R = ca/\nu$ = Reynolds number

$\sigma = z/aR$ = dimensionless axial co-ordinate

σ' = value of σ corresponding to $\lambda_0 = 1.98$

g_3 = the z component of the acceleration of gravity

p = static pressure at the point x, y, z

p_0 = static pressure at the inlet section $z = 0$

Δp = pressure drop between the still liquid in the supply reservoir and the section z

m = dimensionless constant which defines the pressure drop in the transition length

α, β = certain parameters which are functions of z alone

$\gamma = \beta a$ = dimensionless parameter

$I_n(x) = i^{-n}J_n(ix)$, where $i = \sqrt{-1}$, and J_n is the nth-order Bessel function.[7] Throughout this paper the argument of the I functions is γ if not otherwise indicated

The Family of Velocity Profiles

The Navier-Stokes equation for w is

$$dw/dt = g_3 - (1/\rho)(\partial p/\partial z) + \nu(w_{xx} + w_{yy} + w_{zz}) \quad [1]$$

The following three approximations, which are common to the theories of Boussinesq, Schiller, and Atkinson-Goldstein, will be employed in the present theory:

1 Over the inlet section $z = 0$, the velocity component w is constant and equal to the mean velocity c. Nikuradse's[6] test curves thoroughly justify this assumption for the case of tubes which are provided with short bell-shaped mouths.

2 The pressure gradient $-\partial p/\partial z$ is a function of z alone.

3 The term νw_{zz} may be neglected in Equation [1]. This is tantamount to the assumption that the derivative of the normal stress $\partial\sigma_z/\partial_z$ is the same as the pressure gradient $-\partial p/\partial z$.

In addition to these assumptions, there is introduced the fourth condition

$$dw/dt = \nu\beta^2 w \quad [2]$$

where β is a function of z alone. The purpose of this approximation is to reduce Equation [1] to a linear form. It can be partially justified on theoretical grounds. In the first place, Equation [2] is satisfied by $\beta = 0$ in the permanent regime beyond the transition length. Also, this equation is satisfied, irrespective of the value of β, at all points on the wall of the tube, since w and dw/dt both vanish there. Furthermore, if it is assumed with Schiller[4] and Atkinson-Goldstein[5] that the laminar state is attained by the development of a boundary layer in the transition length, then the conclusion is reached that Equation [2] is satisfied at all points in the undisturbed central core of fluid. This conclusion emerges from the fact that the derivatives w_x and w_y vanish over the flat central portions of the velocity profiles, and accordingly the acceleration $dw/dt = uw_x + vw_y + ww_z$ reduces to $dw/dt = ww_z$. Since w is a function of z alone in the central core, w_z is likewise a function of z alone in that region, and it follows that Equation [2] is there satisfied by $\nu\beta^2 = w_z$. Finally, it may be concluded from this that Equation [2] is satisfied at all points of the inlet section $z = 0$, since the depth of the boundary layer there reduces to zero. Thus, Equation [2] is justified, except for those points which lie within the boundary layer. Of

Presented at the National Meeting of the Applied Mechanics Division, Philadelphia, Pa., June 20–21, 1941, of The American Society of Mechanical Engineers.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until July 10, 1942, for publication at a later date. Discussion received after the closing date will be returned.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

[7] For tables of the I functions see, for example, "Theory of Bessel Functions," by G. N. Watson, Cambridge University Press, London, England, 1922. "Bessel Functions," by Andrew Gray, G. B. Mathews, and T. M. MacRobert, Macmillan and Co., Ltd., London, England, second edition, 1922.

course, in the latter part of the transition length, a true boundary layer does not exist, since the central parts of the velocity profiles are appreciably rounded. However, in that region, the flow approaches the laminar state for which Equation [2] remains valid.

With the foregoing assumptions, Equation [1] reduces to the form

$$w_{zz} + w_{yy} - \beta^2 w = \alpha \quad [3]$$

where α and β are functions of z alone. This equation will apply for a cylindrical tube of any cross section, but the present discussion is restricted to the circular cross section.

A particular solution of Equation [3] is

$$w = -\alpha/\beta^2 \quad [4]$$

It then suffices to solve the complementary equation

$$V_{zz} + V_{yy} - \beta^2 V = 0 \quad [5]$$

In cylindrical co-ordinates, this reduces to Bessel's equation of order zero

$$V_{rr} + \frac{1}{r} V_r - \beta^2 V = 0 \quad [6]$$

The only solution which is finite for $r = 0$ is $V = KI_0(\beta r)$. Hence

$$w = KI_0(\beta r) - \alpha/\beta^2 \quad [7]$$

The quantities α and K may be eliminated from this equation by means of the boundary condition $w = 0$, and the continuity equation

$$\int_0^a rw dr = (1/2)a^2 c \quad [8]$$

Introducing the dimensionless notation $q = r/a$, $\lambda = w/c$, $\gamma = \beta a$, gives

$$\lambda = [I_0(\gamma) - I_0(\gamma q)]/I_2(\gamma) \quad [9]$$

This is the equation of the family of velocity profiles. It remains to express the parameter γ of this family of curves as a function of z.

The Function $\gamma(z)$

The problem of expressing the parameter of a known family of velocity profiles as a function of the axial co-ordinate is treated in the paper by Schiller.[4] In fact, Schiller assumes the velocity profiles to be straight-line segments terminated by parabolic arcs, and he obtains the parameter of this family as a function of z by applying the momentum equation to the whole body of fluid, and Bernoulli's equation to the central core. Essentially the same treatment is given here but, instead of using the simple Bernoulli equation, the two viscosity terms νw_{zz} and νw_{yy} in the Navier-Stokes equation are retained, since they are important for the latter part of the transition length. These terms are irrelevant in Schiller's treatment, since, by his hypotheses, they vanish.

The momentum equation, which can be obtained by integrating the Navier-Stokes equation over the cross section, is

$$2\nu \int_0^a (rw_{rr} + w_r)dr + a^2 g_3 - \frac{a^2}{\rho}\frac{dp}{dz} = 2\frac{d}{dz}\int_0^a w^2 r dr \quad [10]$$

By means of Equation [9], the first integral may be evaluated, giving

$$-\frac{2\nu c\gamma I_1(\gamma)}{I_2(\gamma)} + a^2\left(g_3 - \frac{1}{\rho}\frac{dp}{dz}\right) = 2\frac{d}{dz}\int_0^a w^2 r dr \quad [11]$$

The term $g_3 - (1/\rho)dp/dz$ may be eliminated by means of the Navier-Stokes equation[5]

$$g_3 - \frac{1}{\rho}\frac{dp}{dz} = w_0\frac{dw_0}{dz} - \nu(w_{rr} + \frac{1}{r}w_r)_0 \quad [12]$$

where the subscript zero refers to the central axis. Equations [9] and [12] yield

$$g_3 - \frac{1}{\rho}\frac{dp}{dz} = w_0\frac{dw_0}{dz} + \frac{\nu c\gamma^2}{a^2 I_2(\gamma)} \quad [13]$$

Substituting this relation in Equation [11] gives an equation which may be expressed in the following dimensionless form

$$\frac{2\gamma I_1(\gamma) - \gamma^2}{I_2(\gamma)} = \frac{d}{d\sigma}\int_0^1 (\lambda_0^2 - 2\lambda^2)q\, dq \quad [14]$$

Also, by Equation [9]

$$\int_0^1 (\lambda_0^2 - 2\lambda^2)qdq = \frac{(I_0 - 1)^2 - 4I_0 I_2 + 2I_1^2}{2I_2^2} \quad [15]$$

in which the argument of the I's is γ. It is convenient to use the abbreviations

$$\left.\begin{aligned} f(\gamma) &= [4I_0 I_2 - (I_0 - 1)^2 - 2I_1^2]/2I_2^2 \\ g(\gamma) &= I_2/(2\gamma I_1 - \gamma^2) \end{aligned}\right\} \quad [16]$$

Equation [14] then may be expressed

$$1/g(\gamma) = -f'(\gamma)d\gamma/d\sigma \quad [17]$$

This is a differential equation which determines γ as a function of σ.

By means of the asymptotic formula

$$I_n(x) = \frac{e^x}{(2\pi x)^{1/2}}[1 + \epsilon_n(x)], \quad \lim_{x\to\infty}\epsilon_n(x) = 0 \quad [18]$$

there results from Equation [9] $\lim_{\gamma\to\infty}\lambda = 1$. Since $\lambda = 1$ at the inlet section $z = 0$, then $\lim_{\gamma\to\infty} z(\gamma) = 0$. Hence, Equation [17] yields

$$\sigma = \int_\gamma^\infty g(\gamma)f'(\gamma)d\gamma = \int_\gamma^\infty g(\gamma)df(\gamma) \quad [19]$$

For the numerical integration of this equation, make the change of variables

$$X = f(\gamma), \quad Y = g(\gamma) \quad [20]$$

By the power series and the asymptotic series for the I functions the following limits are established

$$\left.\begin{aligned} X &\to 1/2,\ Y \to 0 \text{ as } \gamma \to \infty \\ X &\to -2/3,\ Y \to \infty \text{ as } \gamma \to 0 \end{aligned}\right\} \quad [21]$$

Equation [19] may then be expressed

$$\sigma = \int_X^{1/2} Y dX \quad [22]$$

Equation [20] may be regarded as the parametric equations of a curve, and Equation [22] shows that the function $\sigma(\gamma)$ is represented by the area under this curve in the interval $(X, 1/2)$. By assigning a set of values to γ, a table of points on the curve may be computed, which gives, by numerical integration, the corresponding values of σ. The values of σ in Table 1 are computed

[5] Schiller here employed the Bernoulli equation. This is obtained from Equation [12] by dropping the viscosity terms.

in this way. The values of λ_0 are computed directly from Equation [9].

This table, with Equation [9], completely defines the velocity field in the transition length. The value $\sigma = \sigma'$, corresponding to $\lambda_0 = 1.98$, was called by Boussinesq the "length of transition." From Table 1 it follows $\sigma' = 0.23$.

The Pressure Drop

In the transition length, the pressure gradient $-dp/dz$ is higher than in a region of laminar flow, not only because of the increased frictional loss, but also because the kinetic energy of the liquid increases as it passes downstream. To evaluate the pressure drop, consider the energy equation. The power which is dissipated by fluid friction in the interval $z = 0$ to $z = z$ is[9]

$$E = \mu \int_0^z dz \int_\omega [2(u_x^2 + v_y^2 + w_z^2) + (w_y + v_z)^2 + (u_z + w_x)^2 + (v_x + u_y)^2] d\omega \quad \ldots [23]$$

It is assumed that the lateral velocity components u and v may be neglected in this equation. Then the continuity equation $u_x + v_y + w_z = 0$ shows that consistently the term w_z may be neglected, so that the preceding equation reduces to

$$E = \mu \int_0^z dz \int_\omega (w_x^2 + w_y^2) d\omega \quad \ldots [24]$$

By a theorem of Helmholtz,[10] the laminar velocity distribution furnishes a minimum to the integral [24], and accordingly the friction loss is always higher in the transition length than it is in the permanent regime further downstream.

During a time interval dt, the net work of pressure on the body of fluid in the interval $z = 0$ to $z = z$ is $c\omega(p_0 - p)dt$. The work of friction on this body of fluid is $-Edt$, where E is given by Equation [24]. It is assumed that the tube is horizontal, so that the work of body force is zero. Then, equating the work of all forces to the change in kinetic energy gives the energy equation

$$c\omega(p_0 - p) = \mu \int_0^z dz \int_\omega (w_x^2 + w_y^2) d\omega + (1/2)\rho \int_\omega (w^2 - c^2) d\omega \quad \ldots [25]$$

For the circular cross section, this may be expressed

$$\frac{p_0 - p}{(1/2)\rho c^2} = 2 \int_0^1 (\lambda^3 - 1) q \, dq + 4 \int_0^\sigma d\sigma \int_0^1 \lambda_q^2 q \, dq \quad \ldots [26]$$

By Bernoulli's equation, the pressure drop that occurs in the mouth of the tube is $(1/2)\rho c^2$. Accordingly, the total drop Δp between the supply reservoir and the section z is $(1/2)\rho c^2 + (p_0 - p)$. Equations [9] and [26] then give

$$\frac{\Delta p}{(1/2)\rho c^2} = 1 + 2 \int_0^1 (\lambda^3 - 1) q dq + 2 \int_0^\sigma \frac{\gamma^2}{I_2^2} (I_1^2 - I_0 I_2) d\sigma \quad \ldots [27]$$

Curve 2—Plotted from Table 2
Curve 3—Calculated by Schiller's formula
Curve 4—Calculated by Boussinesq's formula

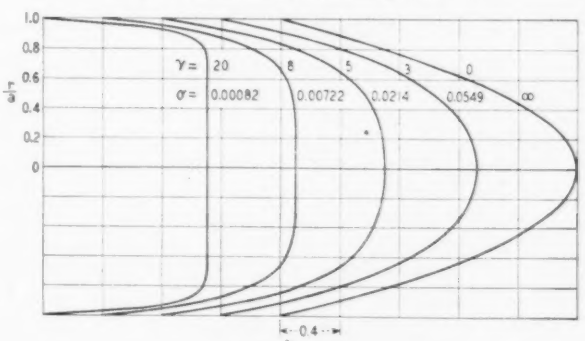

FIG. 2 VELOCITY PROFILES
(Computed by Equation [9] and Table 1.)

It is convenient to denote the integrand $(\gamma^2/I_2^2)(I_1^2 - I_0 I_2)$ by $\phi(\gamma)$. The evaluation of the integral of this function involves a difficulty, due to the fact that the integrand becomes infinite when $\sigma \to 0$. However, the relation $\lim_{\gamma \to \infty} \gamma^2\sigma = 1/4$ (which may be derived from Equation [19]), and the asymptotic formula

$$\phi(\gamma) \sim \gamma + 3 + \frac{5}{\gamma} + \frac{7}{\gamma^2} + \ldots \quad [28]$$

gives $$\int_0^{0.0426} \phi(\gamma)d\sigma = 0.00518 \quad [29]$$

($\sigma = 0.000026$ corresponds to $\gamma = 100$).

Hence

$$\int_0^{\sigma} \phi(\gamma)d\sigma = 0.00518 + \int_{0.0426}^{\sigma} \phi(\gamma)d\sigma \quad [30]$$

Since $\int_{0.0426}^{\sigma} \phi(\gamma)d\sigma$ is a proper integral, it may be evaluated by numerical methods. Also, the integral $\int_0^1 (\lambda^3 - 1)qdq$ may be calculated by Simpson's rule from Equation [9]. With Equation [27], Table 2 is then obtained.

From this table we may plot a curve of $\Delta p/(1/2)\rho c^2$ against σ. This curve determines the pressure drop Δp as a function of z. The slope of the curve is

$$-\frac{dp/d\sigma}{(1/2)\rho c^2} = -\frac{a^2}{(1/2)\rho v c}\frac{dp}{dz} \quad [31]$$

In the region of laminar flow, $dp/dz = -8c\rho\nu/a^2$. Consequently, the curve is asymptotic to a line with slope 16.

If a value σ_1 is chosen somewhat greater than the length of transition σ', and if $\sigma > \sigma_1$, Equation [27] may be expressed in the form

$$\frac{\Delta p}{(1/2)\rho c^2} = 1 + 2\int_0^1 (\lambda^3 - 1)qdq + 2\int_0^{\sigma_1} \phi(\gamma)d\sigma + 2\int_{\sigma_1}^{\sigma} \phi(\gamma)d\sigma \quad [32]$$

But, for $\sigma > \sigma_1$, $\lambda = 2(1 - q^2)$ (Poiseuille flow), and consequently $\int_0^1 (\lambda^3 - 1)q\,dq = 1/2$. Also, from the power series for the I functions, $\gamma^2/I_2 \to 8$ and $(I_1^2/I_2) - I_0 \to 1$ as $\gamma \to 0$. Since $\gamma \to 0$ as $z \to \infty$, it follows

$$\int_{\sigma_1}^{\sigma} \phi(\gamma)d\sigma = 8(\sigma - \sigma_1) \quad [33]$$

Hence, setting $\int_0^{\sigma_1} \phi(\gamma)d\sigma = K$, gives

$$\Delta p/(1/2)\rho c^2 = 16\sigma + 2K + 2 - 16\sigma_1 \quad [34]$$

Setting $2K + 2 - 16\sigma_1 = m$, this equation may be expressed in the form

$$\Delta p = \frac{8\mu cz}{a^2} + (1/2)m\rho c^2 \quad [35]$$

This is a fundamental equation in the theory of tube-type viscosimeters. If $\sigma_1 = 0.304$, Table 2 shows $K = 2.574$. Hence

$$m = 2.28 \quad [36]$$

Conclusions

The velocity field in the transition length is completely defined by Equation [9] and Table 1. The curves of Fig. 1 give a comparison of the center-line velocities as computed by this theory, and by the theories of Boussinesq[3] and Schiller,[4] and as observed by Nikuradse.[6] From Nikuradse's curve, the computed length of transition $\sigma' = 0.23$, appears to be in close agreement with experiment. A few of the computed velocity profiles are shown in Fig. 2.

The pressure function in the transition length is defined by Table 2. However, if the coordinate z is greater than the length of transition, the pressure drop Δp is given by Equation [35], in which, according to the present theory, $m = 2.28$. The most suitable value for this constant has not been well established by experiment. Schiller computed $m = 2.16$, but he says that this value seems to be too low. In four runs, he obtained the experimental values 2.115, 2.35, 2.36, and 2.45—average 2.32.[11] Other experimental results have been given by Riemann,[12] who obtained values ranging from 2.220 to 2.268—average 2.248 ± 0.012. Accordingly, he recommends for viscosimetry practice the value 2.24, which was computed by Boussinesq. Atkinson and Goldstein[5] computed $m = 2.41$, but this value appears to be high.

Model Tests of Two Types of Vibration Dampers

By C. A. MEYER[1] and H. B. SALDIN,[2] PHILADELPHIA, PA.

This paper deals with the construction and tests of two types of vibration dampers, selected from a number of original proposals, designed to damp out the vibration in steam-turbine impulse blades. These dampers were tested using models constructed of such size and physical dimensions as to simulate the conditions of operation in the actual turbine blade. Test results show that if a properly designed damper is attached to a freely vibrating system having 26 times the mass of the damper, it will reduce an initial deflection of the vibrating system to 4 per cent of its value in 10 cycles.

Nomenclature

The following nomenclature is used in the paper:

A = initial amplitude ratio $= x_0/D$
D = $2R$ = diameter of cylinder or hemispherical cup
d = $2r$ = diameter of roller or sphere
F = frequency of main system
f = frequency of damper $= \frac{1}{2\pi}\sqrt{C\,\frac{G}{(R-r)}\left(1-\frac{\rho}{\gamma}\frac{h}{D}\right)}$
($C = {}^2/_3$ for cylindrical, $C = {}^5/_7$ for spherical damper)
G = acceleration due to force field
= centrifugal acceleration in a rotating system
g = acceleration of gravity
H = fluid depth ratio $= h/D$
h = height of fluid in chamber
L = aspect ratio $= l/D$
l = length of roller
M = mass of main system (effective)
m = mass of damper
N = viscosity number $= \nu\sqrt{\frac{1}{GD^3}}$
n = number of cycles
P = density ratio $= \frac{\rho}{\gamma}$
R = groove-size number $= r_m/D$
r_m = $\frac{\text{cross-section area of groove}}{\text{wetted perimeter}}$ = hydraulic radius of groove
X = amplitude ratio $= x/x_0$
x_0 = initial amplitude of vibration
x = amplitude of vibration after n cycles; double amplitude $= 2x$
γ = density of roller or ball material
δ = logarithmic decrement of main system without damper
μ = absolute viscosity
$\nu = \frac{\mu}{\rho}$ = kinematic viscosity
ρ = density of fluid
Φ = mass ratio $= M/m$
ψ = frequency ratio $= f/F$
Ω = frequency number $= F\sqrt{D/G}$

Introduction

Two principal problems are considered in this paper. The first is concerned with the development of a method of testing blade-vibration dampers. The second has to do with the actual testing of the performance of two types of dampers. Due to the obvious difficulties which are encountered in testing the dampers in a rotating turbine blade, it appears attractive to investigate the fundamental behavior of the different dampers in a nonrotating test setup. In order to accomplish this, the methods of dimensional analysis have been applied to insure similarity between the conditions of operation of the dampers in the rotating turbine blade and those in a nonrotating model.

The two types of dampers described in the paper operate on the same principle. These dampers are intended to act as damped-vibration absorbers.[3] They consist fundamentally in connecting an auxiliary vibration system (the damper) to the main vibration system (for instance, the turbine blade), which we desire to be free from vibration.

For best operation, it has been found by means of theoretical calculations that the auxiliary system should be arranged to have a natural frequency of vibration very nearly equal to that of the main system. Also, it has been found that by introducing a proper amount of damping between the auxiliary and main systems, the combined system will become less affected by variations of the frequency of the exciting force. These characteristics of the damped-vibration absorber are well known and are shown more clearly by Den Hartog.[4]

The foregoing characteristics have been obtained through the theoretical calculation of the system consisting of an absorber attached to a main vibrating system which is *continuously excited*. The calculation of an absorber-vibration system which is *freely vibrating* is mathematically cumbersome. Therefore, no general characteristics have so far been obtained for the nonsteady vibration. However, we might expect that the best damper performance for the freely vibrating system would be obtained for some optimum tuning between the damper and the blade and also for some optimum value of damping between the auxiliary and main system. Thus, the principal purpose of testing the dampers has been to determine for the freely vibrating system:

1 The rate of vibration decay for the different damper constructions.

Vibration Dampers

Fig. 1 is a sketch of the so-called spherical damper. This damper consists of a spherical ball *a* which is placed in a capsule *b*. The capsule has a hemispherical end *c*, which has a slightly larger radius than the ball. A small amount of fluid is placed in the capsule and then the capsule is suitably sealed. The capsule is finally fastened in the blade shroud *d*. Under the action

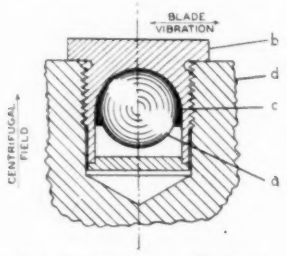

Fig. 1 Spherical Damper

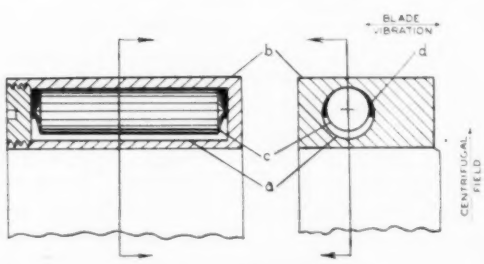

Fig. 2 Cylindrical Damper

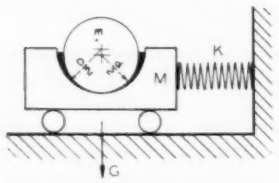

Fig. 3 Vibration Damper
(See Appendix 1.)

of the centrifugal field, due to the rotation of the blade, the spherical ball and the damping fluid are forced against the cup-shaped end of the capsule. The ball in this position will then have a natural frequency of vibration in the cup. In fact, by selecting suitably the radii of the ball and the cup, the natural frequency of the ball vibrating in the cup can be made to match the natural frequency of the blade. Thus, the ball in its cup acts as an auxiliary vibration system attached to the turbine blade. The fluid surrounding the ball supplies the damping between the auxiliary system (the ball) and the main system (the blade). It is further to be noted that the spring or restoring force of the auxiliary system is really supplied by the mass forces acting on the ball rather than by an actual spring. This fact eliminates one disadvantage of dynamic-vibration absorbers, namely, the large stresses which usually occur in the spring of the auxiliary system.

Fig. 2 is a sketch of a cylindrical damper which performs in the same manner as the spherical damper. In this case, a cylindrical roller in a cylindrical hole is used in place of a ball in a cup. This damper is constructed by drilling a hole *a* in the blade shroud *b*. The roller *c*, and a small amount of damping fluid *d*, is suitably sealed in the hole. Using this construction, a damper having a larger mass can be placed in a given available space. However, this damper is effective against vibration in only one direction. During the tests of the cylindrical damper, it was found that by cutting grooves in the surface of the roller a better performance could be obtained. Thus the grooved cylindrical roller was developed.

Theory Used in Constructing Damper Models

The actual size and frequency of the damper models have been obtained after first deciding on the variables on which the damper performance principally depends. The variables chosen to represent the damper performance have been obtained by means of the dimensional analysis in Appendix 1. The analysis shows that, within the accuracy desired, there exists a relation between the variables, represented as follows

$$\text{A function of } [X, n, \Omega, N, \Phi, \psi, L, R, \delta] = 0 \quad \ldots [1]$$

where the variables are defined in the nomenclature. The relation Equation [1] simply states that the dimensionless amplitude X principally depends upon the number of cycles of vibration, after release n, the dimensionless frequency of the main system Ω, the dimensionless viscosity of the damping fluid N, the ratio of the mass of the main system to that of the damper Φ, the ratio of the natural frequencies of the auxiliary and main vibrating systems ψ, the ratio of length to diameter of the damper roller L, the dimensionless groove size R, and the logarithmic decrement δ of the main system without the damper.

If we test a model using values of the dimensionless variables which are the full-scale values, the relation, for instance, between the dimensionless amplitude $X = (x/x_0)$ and the number of cycles n obtained in the model test, should be the same[5] as that for the full-scale damper. For instance, it is possible to test the model with the full-scale value of the dimensionless frequency term $\Omega = F\sqrt{D/G}$. Since the value of G in the turbine damper is roughly 5000 times that in the model, we can suitably adjust the size D and the frequency F to obtain the full-scale value of $\Omega = F\sqrt{D/G}$. The model size and frequency have been chosen so that there will not be too great a difference between the viscosity ν in the model and in the full-scale damper. An examination of the definition of the dimensionless viscosity number N should clarify this point.

The tests of the dampers were carried out with a few values of the dimensionless frequency term Ω which approximate the full-scale value. Several values of the dimensionless viscosity term N were tested in order to obtain the optimum value of this term for each of three values of tuning $\psi = (f/F)$. The tested values of $\Phi = (M/m)$, $L = (l/D)$, $A = (x_0/D)$ were approximately the full-scale values. The damping δ of the main system could not be controlled. However, the best damping curve for each type

TABLE 1 RANGE OF VALUES OF DIMENSIONLESS VARIABLES FOR TURBINE DAMPER

Dimensionless variable	Approximate range in turbine	Tested range, spherical damper	Tested range, cylindrical damper
$\Omega = F\sqrt{D/G}$	0.58– 2.1	0.835– 1.27	0.657– 0.877
$N \times 10^3 = \left(\nu\sqrt{\frac{1}{GD^3}}\right) \times 10^3$	[a]	1.45 –12.70	1.47 –29.4
$\Phi = (M/m)$	50 –10	23.2 –19.2	28.4 –24.2
$\psi = (f/F)$	0.7 – 1.3	0.58 – 1.26	0.85 – 1.14
$A \times 10^3 = \left(\frac{x_0}{D}\right) \times 10^3$	4 –20	8.19 – 9.17	8.34 –11.1
$R = (r_m/D)$	.....	.....	0 – 0.02

[a] The value of this term should be the optimum value determined by the model test.

[5] This statement is true if no important variable has been overlooked in writing Equation [1*a*], Appendix 1.

of damper was later corrected for the damping in the main system to give a comparison of the dampers for the case when the main system has no damping. Table 1 gives the approximate range of the values of the dimensionless variables for a damper in a turbine, together with the range of values covered by the tests.

Test Method

The method of testing the different dampers consisted principally in mounting them on a vibration system composed of a mass supported on four flat cantilever springs as shown in Fig. 4. The vibration system was deflected to a given amplitude and then released by a trigger *E*, Fig. 4. The variation of the amplitude of vibration with the number of cycles was measured using one of the following methods:

1 An arc light reflecting from a mirror *C*, Fig. 4, mounted on the center of a flat strip of metal, one end of which was held stationary, the other end being attached to the vibrating system. The reflection from the mirror was focused on a moving photographic film in an oscillograph.

2 A recording stylus connected to the vibrating system and recording on moving wax paper *F*, Fig. 4.

The cup *A*, Fig. 4, is the model of the spherical damper. The bottom of this cylindrical cup is made hemispherical. The steel

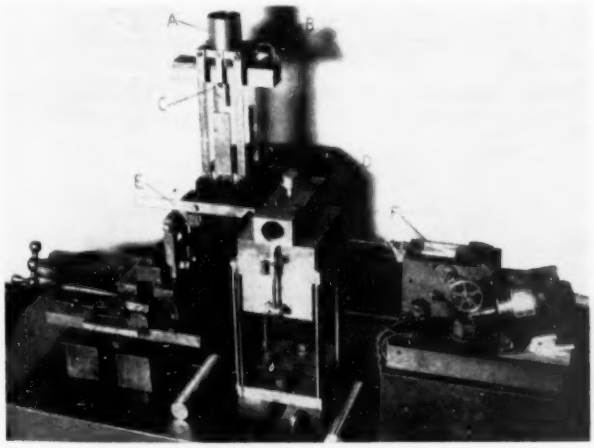

Fig. 4 Model-Test Arrangement

ball shown in the illustration is placed in this cup together with the damping fluid. The mirror *C* was used, together with a spotlight and a rotating photographic film to record the vibration decay. The weights, upon which the spherical ball rests in Fig. 4, were used to adjust the mass ratio of the vibrating system.

The arrangement *D* in Fig. 4 is the model of the cylindrical damper. The two cylindrical rollers (smooth and grooved) together with one of the two caps used to close off the ends of the cylindrical hole can be seen in the foreground. Three different groove sizes were tested. During the tests of the cylindrical damper, the recording system *F* was employed. This system was used in place of the photographic method in order to avoid the delay involved in developing films. This recording system consisted of a scriber arm mounted on an elastic hinge. The record was taken on wax paper driven over a flat surface by means of the motor gear mechanism shown.

The damping fluids used in the model tests were mixtures of kerosene and oil or oil and mineral spirits, in varying proportions, depending upon the viscosity desired. Acetone was also used in some of the tests.

The dampers were thoroughly cleaned with ether or carbon

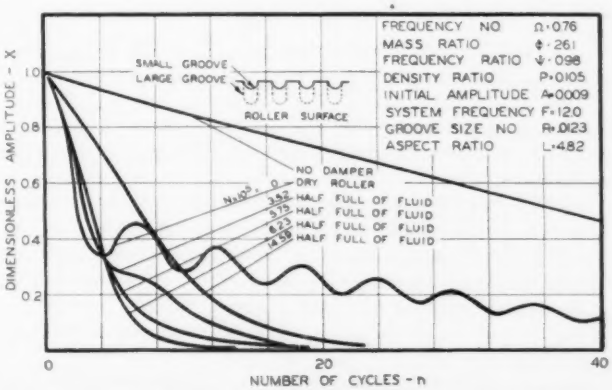

Fig. 8 Typical Curves of Vibration Amplitude of Grooved Cylindrical Damper

tetrachloride whenever the fluid was changed. Also the fluids were filtered before being used in the dampers. These precautions were found necessary in order to duplicate test results. The fluid viscosities were obtained by means of a rotating-disk viscosimeter. The frequency of the vibrating system was determined by means of a strobotac or by a timing wave on the recording tape.

Results of Model Tests

The curves shown in Figs. 5, 7, and 8 are typical curves obtained from the model tests. On these curves, the envelope of the vibration record has been plotted against the number of cycles of vibration after release. Originally it was the authors' intention to calculate the logarithmic decrement from the tests of the dampers. However, the decrement was found to vary so widely with amplitude (or number of cycles) that it appeared more instructive to plot the envelope of the vibration record against the number of cycles.

Fig. 5 shows typical vibration-record envelopes obtained from the tests of the spherical damper for one value of tuning ($\psi = 0.91$) and for different values of fluid viscosity N. On this curve is also shown the results of tests when the cup is half-filled with fluid ($H = 0.5$), and also using 1 or 5 drops of fluid. The difference between the performance when the sphere is covered with fluid and when using 1 or 5 drops of fluid is surprising.

Fig. 6 is a cross-plot of several curves similar to those of Fig. 5. The cross-plots were arbitrarily taken at 10 cycles. The curves, Fig. 6, show that the optimum value of the viscosity number is not very critical, e.g., a considerable variation in viscosity number is permissible in order to obtain optimum performance. In Fig. 10 is a cross-plot of Fig. 6, taken at the point of optimum viscosity number N. This curve shows the effect of tuning on the amplitude ratio at 10 cycles. The optimum tuning occurs for $\psi = 1$ which is similar to that for the steady-state operation of a tuned dynamic-vibration absorber. It is also seen from this curve that the damper is effective over a wide range of frequency ratios, ψ.

Typical curves obtained from the tests of the cylindrical-damper model are given in Fig. 7. A study of these curves reveals that, with the damper half-full of fluid, there is too much damping of the roller even when the lightest (least viscous) fluid available (acetone) is used. Further, the best performance of the damper occurs, as is the case with the spherical dampers, when using a small amount of fluid (1 drop).

After examining the curves in Fig. 7 together with other curves showing the damper performance at different tuning ratios ψ, it was suggested to groove the roller so that optimum performance might possibly be obtained with the roller half-covered with fluid and also while using a fluid having a greater viscosity than acetone.

An example of some of the records obtained with the grooved cylindrical roller is given in Fig. 8. Here, with the roller half covered with fluid, it was possible to determine the optimum viscosity number N with the fluids available for test. It is also to be noted that, with the smaller viscosities, beats occurred in the vibration record.

Fig. 9 shows a typical cross-plot taken arbitrarily at 10 cycles from five groups of curves similar to Fig. 8; the five groups of curves being the results of tests with five different tuning ratios ψ, and for one value of groove size ($R = 0.02$). The curves, Fig. 11, have been obtained from a set of four curves similar to those of Fig. 9, each set of curves representing tests with a different groove size, R.

Referring to Fig. 9, for instance, the optimum viscosity has been taken as the viscosity giving the minimum amplitude ratio (x/x_0) at 10 cycles. The curves, Fig. 11, show as might be

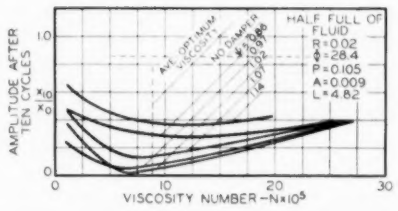

Fig. 9 Cylindrical Damper: Effect of Fluid Viscosity on Amplitude for Various Frequency Ratios

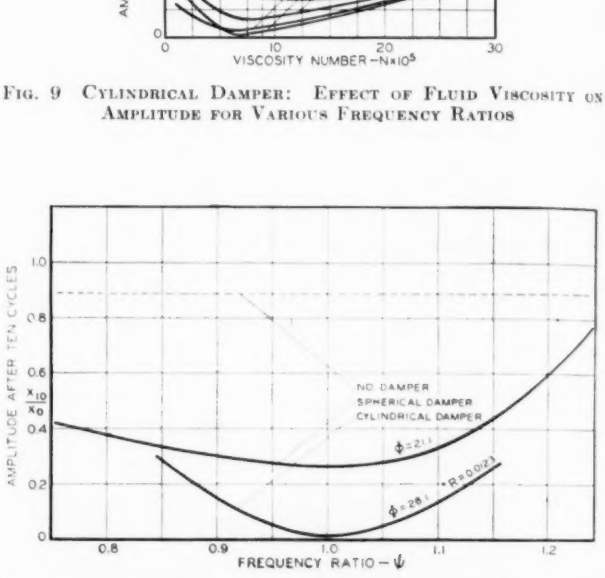

Fig. 10 Spherical and Cylindrical Dampers: Effect of Tuning on Amplitude With Fluid Having Optimum Viscosity

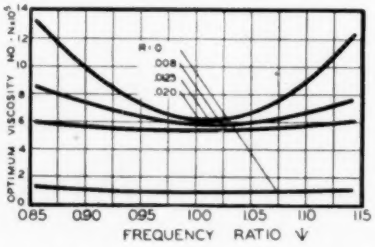

Fig. 11 Cylindrical Damper: Variation of Optimum Viscosity With Tuning and Groove Size

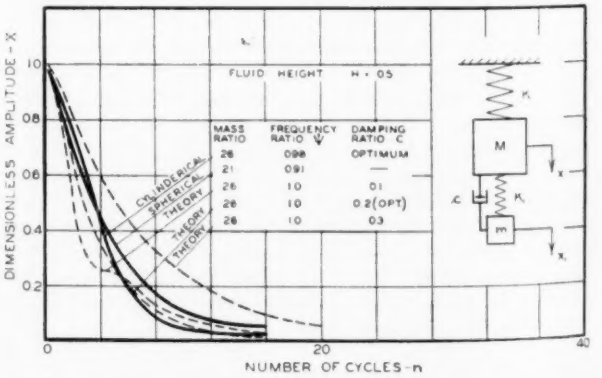

Fig. 12 Spherical and Cylindrical Dampers: Test Curves for Optimum Conditions After Correcting for Inherent Damping of Main System, and Theoretical Curves for the System Shown

expected that the larger the groove size the greater the optimum viscosity. Also, when the damper is not tuned ($\psi \neq 1$), a greater fluid viscosity is required for optimum damper performance. The lower curve in Fig. 10 is a typical curve for the grooved roller, showing the effect of varying the tuning ratio ψ on performance. The fact that the two curves in Fig. 10 are relatively flat is helpful when it is considered that some uncertainty may exist in predicting the natural frequency of the main system to which the dampers are attached.

The best tested performances of the spherical and cylindrical dampers are given in Fig. 12. These curves have been obtained by correcting the actual test results for the damping which was inherent in the main vibration system of the models. A step-by-step graphical integration was carried out, in which the actual vibration record was corrected for the energy absorbed in the main vibration system. The energy absorbed by the main system was determined from a vibration record of the main system without the damper.

The curve, Fig. 12, shows that if a cylindrical damper is placed in a vibrating system having 26 times the mass of the damper, it will reduce an initial deflection of the vibrating system to 4 per cent of its value in 10 cycles.

The dashed-line curves, Fig. 12, have been calculated for an assumed vibration system shown in Fig. 12. The method of calculating these curves is outlined in Appendix 2.

Acknowledgment

The authors wish to express their appreciation for the valuable assistance given them by Mr. R. P. Kroon in the various phases of this work.

Dimensional Analysis

The purpose of the dimensional analysis is to determine what conditions must be met if we are to test the dampers described, using models which are subjected to terrestrial gravity g, as compared to the high centrifugal field which the dampers would experience in the rotating turbine blade.

Let us assume that we have the system, shown in Fig. 3, p. A-60, consisting of a mass M and spring system K (representing the blade) and a roller or ball m, in a cup or cylinder (representing the damper).

The entire system is in a gravity field expressed by acceleration G. Suppose the mass M is held to one side of the equilibrium position and then suddenly released. Upon what factors does the amplitude of vibration principally depend?

We can say that the amplitude will be some function of the variables, represented as follows

$$x = f\,(G, D, d, M, m, F, \mu, \rho, \gamma, x_0, n, \delta) \ldots\ldots [1a]$$

where the variables are as defined in the nomenclature.

By applying the methods of dimensional analysis[6] it is possible to replace the relation Equation [1a] by another relation containing a smaller number of dimensionless variables.

The theory of dimensional analysis also permits the selection of many different forms for the dimensionless variables. In the present case, we have selected the following forms of the variables and write the relation

$$\text{A function of}\left[X, n, \Omega, N, \Phi, P, A, \left(\frac{m}{\rho D^3}\right), \left(\frac{d}{D}\right), \delta\right] = 0 \ldots [2]$$

which replaces relation Equation [1a] and which is equally as valid as that relation, although it contains three less variables.

In order to determine completely the performance of the tuned dampers previously described, we must find the functional relation Equation [2] for the particular damper, either by calculation or by test.

Obviously, it is impossible to test in a reasonable time the effect of wide variations of all the variables in Equation [2]. For this reason an attempt is made to alter or eliminate some of the variables in Equation [2] by using some other information or assumptions.

The theoretical natural frequency of a sphere in a cup (or a cylinder in a cylindrical hole) without fluid is given by

$$f = \frac{1}{2\pi}\sqrt{C\frac{2G}{D-d}} = \frac{1}{2\pi}\sqrt{\frac{G}{D}}\sqrt{\frac{2C}{1-(d/D)}} \ldots\ldots [3]$$

where

$C = 5/7$ for a sphere

$= 2/3$ for a cylinder

since $F\sqrt{(D/G)} \equiv \Omega$

we write

$$(f/F) = \frac{1}{2\pi\Omega}\sqrt{\frac{2C}{1-(d/D)}} = \text{a function of } \Omega \text{ and } (d/D) \ldots [4]$$

by means of Equation [4], we can replace (d/D) in Equation [2] by (f/F). Further, the dimensionless variable $m/(\rho D^3)$ which is related to the loss of weight of the sphere or cylinder due to floating in the damping fluid is eliminated by noticing that for the sphere

$$m = \frac{4}{3}\pi(d/2)^3 \times \gamma$$

and

$$m/(\rho D^3) = \frac{\pi}{6}(d/D)^3\,(\gamma/\rho)$$

Since from Equation [4] (d/D) is a function of (f/F) and Ω we can write

$$m/(\rho D^3) = \text{a function of } (f/F), \Omega, \text{ and } (\rho/\gamma) \ldots\ldots [5]$$

By means of this relation, we can eliminate $m/(\rho D^3)$ from Equation [2].

For the cylindrical damper a procedure similar to the foregoing is easily carried out giving

$$m/(\rho D^3) = \text{a function of } (f/F), \Omega, (\rho/\gamma), \text{ and } (l/D)$$

where l is the length of the roller.

The term (l/D) together with any other geometrical dimensionless variable should also be incorporated in Equation [2]. With these substitutions we thus obtain the variables

$$\text{A function of } [X, n, \Omega, N, \Phi, \psi, P, A, L,^* \delta] = 0 \ldots [2a]$$

A further simplification has been introduced into Equation [2a] by assuming that the only effect of the term $(\rho/\gamma) = P$ on the damper performance is to change the frequency of the damper due to the floating of the sphere or cylinder. Accordingly, we have changed the definition of f to that given in Equation [6]. It is thought that this would introduce slight error, especially as (ρ/γ) for the model is approximately the full-scale value.

$$f = \frac{1}{2\pi}\sqrt{C\frac{2G[1-(\rho/\gamma)\,(h/D)]}{(D-d)}} \ldots\ldots\ldots [6]$$

[6] "Model Experiments and Forms of Empirical Equations," by E. Buckingham, Trans. A.S.M.E., vol. 37, 1915, p. 263; also, "Dimensional Analysis," by P. W. Bridgeman, Yale University Press, New Haven, Conn., 1931.

* This term is used only for the cylindrical damper.

The term (h/D) in Equation [6] has been introduced to take into account the case where the cylindrical or spherical dampers are not completely filled with fluid.

During the tests of the cylindrical damper, it was found that grooving the roller was necessary in order to obtain optimum damping with the fluid viscosities available for test.

The additional term $R = (r_m/D)$ was then added to the list of variables in Equation [2a]. The quantity r_m is the hydraulic radius of the groove cross section.

After introducing these assumptions, Equation [2a] becomes finally

$$\text{A function of}[X, n, \Omega, N, \Phi, \psi, A, L, R, \delta] = 0 \ldots [2b]$$

Appendix 2

Theoretical Calculation of Damper Performance

The differential equations of motion for the vibration system, shown in Fig. 12, are

$$\left.\begin{aligned} M\ddot{x} + kx + k_1(x - x_1) + c(\dot{x} - \dot{x}_1) &= 0 \\ m\ddot{x}_1 + c(\dot{x}_1 - \dot{x}) + k_1(x_1 - x) &= 0 \end{aligned}\right\} \ldots\ldots [7]$$

where x, x_1 = amplitudes of main and auxiliary systems
k, k_1 = spring constants, Fig. 12
c = damping constant of auxiliary system

Numerical solutions of the differential Equations [7] have been found[7] by first assuming the solution to be of the form

$$\left.\begin{aligned} x &= ae^{st} \\ x_1 &= a_1e^{st} \end{aligned}\right\} \ldots\ldots [8]$$

where a, a_1, and s are constants to be determined, and t = time.

Substituting the relations Equations 8 into Equations [7] and also introducing dimensionless variables, we obtain the frequency equation

$$y^4 + 2C\psi\left(1 + \frac{1}{\Phi}\right)y^3 + (1 + \psi^2)y^2 + 2C\psi\left(1 - \frac{\psi^2}{\Phi}\right)y + \psi^2\left(1 - \frac{\psi^2}{\Phi}\right) = 0 \ldots\ldots [9]$$

where $y = (s/\Gamma)$, $C = c/c_c$, $\psi = \dfrac{\omega}{\Gamma}$

$$\Gamma = \sqrt{\frac{k + k_1}{M}} = \text{frequency of main system}$$

$$\omega = \sqrt{\frac{k_1}{m}} = \text{frequency of auxiliary system}$$

$$c_c = 2\pi\omega = \text{critical damping of auxiliary system}$$

The numerical values of the roots of the frequency Equation [9] have been found using Graeffe's root-squaring method. The roots thus obtained are in the form

$$\left.\begin{aligned} y_1 &= -u_1 \pm iv_1 \\ y_2 &= -u_2 \pm iv_2 \end{aligned}\right\} \ldots\ldots [10]$$

A substitution of the roots into Equations [8] yields the expression for the motion of the main system

$$X = e^{-u_1\Gamma t}[A\cos(v_1\Gamma t) + B\sin(v_1\Gamma t)] + e^{-u_2\Gamma t}[D\cos(v_2\Gamma t) + E\sin(v_2\Gamma t)]$$

where $X = x/x_0$ = amplitude ratio of main system, and A, B, D, E are functions of u_1, v_1, u_2, v_2.

Numerical solutions have been carried out using the method outlined with an assumed value of mass ratio Φ of 26 and a value of tuning ratio ψ of unity. The calculations were carried out for each of three values of the damping ratio C.

One assumed value of the damping ratio C was taken as the value which gives optimum damping of the main system, the other two values give a smaller damping of the main system.

The results of the calculations are plotted in Fig. 12. The calculated curves are seen to check closely the tested curves. These curves also show that there is a tendency for beats to occur in the vibration record when the damping of the auxiliary system is less than the optimum value. This same effect has been found by the tests (refer, for instance, to Figs. 5 and 8).

Self-Excited Oscillations in Dynamical Systems Possessing Retarded Actions

By NICHOLAS MINORSKY,[1] CARDEROCK, MD.

There exists a variety of dynamical systems, possessing retarded actions, which are not entirely describable in terms of differential equations of a finite order. The differential equations of such systems are sometimes designated as hysterodifferential equations. An important particular case of such equations, encountered in practice, is when the original differential equation for unretarded quantities is a linear equation with constant coefficients and the time lags are constant. The characteristic equation, corresponding to the hysterodifferential equation for retarded quantities in such a case, has a series of subsequent high-derivative terms which generally converge. It is possible to develop a simple graphical interpretation for this equation. Such systems with retarded actions are capable of self-excitation. Self-excited oscillations of this character are generally undesirable in practice and it is to this phase of the subject that the present paper is devoted.

Introduction

THE forces, or moments, considered in dynamics as functions of parameters, which determine them, are assumed to be instantaneously in phase with these parameters.

For example, a pendulum is acted upon by a couple of gravity $C = mgl \sin \theta$, where θ is the variable parameter, i.e., the angle. The couple C is thus in phase with $\sin \theta$, or θ, for small angles. The differential equations in all such cases are either ordinary differential equations or partial differential equations, as the case may be, but of a finite order.

There exists, however, a rather restricted class of phenomena of the so-called hereditary type, in which the condition of a system at a given instant is determined not only by forces acting at that instant, but depends upon the entire history either of the preceding motion, or the preceding states of the system in general.

V. Volterra has shown that such phenomena can be described mathematically in terms of "integrodifferential equations."

Another variety of systems not entirely describable in terms of differential equations of a finite order are systems possessing "retarded actions." Such systems, designated sometimes as being of a "hysteresis" type, are characterized by the fact that these retarded actions do not depend upon the entire previous history of motion, but merely reproduce variations of corresponding nonretarded actions, or forces, with a certain time lag. The differential equations of such systems are of an infinitely high order. They are designated sometimes as "hysterodifferential equations." So far no general theory for these equations has been developed.

An important particular case of hysterodifferential equations encountered in practical applications is when the original differential equation for unretarded quantities is a linear equation with constant coefficients and the time lags are constant. The characteristic equation, corresponding to the hysterodifferential equation for retarded quantities in such a case, has a series of subsequent high-derivative terms which generally converge. This permits replacing the infinite series of high-derivative terms by its limit which introduces transcendental functions in its expression. Under such circumstances, it becomes possible to give a simple graphical interpretation to this equation.

The most interesting feature of such systems with retarded actions is the fact that they are capable of self-excitation with a theoretically infinite number of frequencies which are determined not only by the parameters of the dynamical system, but also by the parameter of the retarded action, i.e., its time lag.

Such self-excited oscillations are generally undesirable in practice; they are sometimes referred to as "parasitic oscillations" or "hunt."

These oscillations are investigated in this paper.

Systems With a Retarded Action

Retarded actions are generally present in any control system. In fact, a control system B is generally intended to maintain a certain state or level (e.g., of pressure, temperature, voltage, direction in space, rate of motion, etc.) of the system A to be controlled.

A departure of A from its normal state of equilibrium causes B to operate so as to eliminate this initial departure. During this "return-trip" transmission of action (from A to B) and reaction

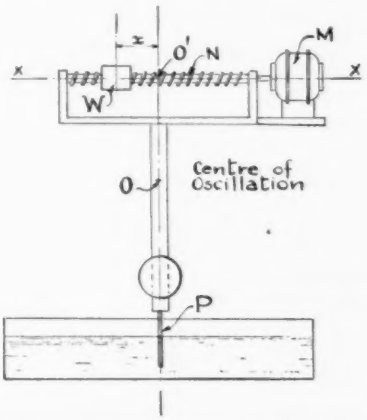

Fig. 1 System of Physical Pendulum in Which Occur Self-Excited Oscillations

(from B to A), a certain time interval Δt elapses, so that the control action, arriving back at A at a certain instant t, does not correspond to the condition of A at this instant but relates to the condition which A had in the past, i.e., at the instant $(t - \Delta t)$.

As an example of a system in which such self-excited oscillation was originally observed, consider a physical pendulum shown in Fig. 1. The differential equation of motion of the pendulum

[1] The David Taylor Model Basin, Bureau of Ships, United States Navy Department.

Presented at the National Meeting of the Applied Mechanics Division, Philadelphia, Pa., June 20–21, 1941, of The American Society of Mechanical Engineers.

Discusson of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until July 10, 1942, for publication at a later date. Discussion received after the closing date will be returned.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

with velocity damping (e.g., produced by a paddle P moving in viscous fluid) is

$$J\ddot{\theta} + B\dot{\theta} + C\theta = 0 \quad [1']$$

where θ is the angle of oscillation and J, B, C are the moment of inertia, the coefficient of the damping, and the "effective spring constant" of the pendulum, respectively.

Assume now that, in addition to the natural damping $B\dot{\theta}$, an artificially produced damping is provided, e.g., a weight w is displaced for that purpose along the axis x-x perpendicular to the axis of the pendulum at O, by means of a motor M acting through a worm N. If the motion of the weight is so controlled[2] that its distance x from the middle point O' is proportional to angular velocity $\dot{\theta}$ of the pendulum, it is clear that the moment of the weight w applied to the pendulum is $wx = S\dot{\theta}$, so that the differential equation of the pendulum is now

$$J\ddot{\theta} + B\dot{\theta} \pm S\dot{\theta} + C\theta = 0 \quad [1]$$

The double sign before $S\dot{\theta}$ means that there are two ways of connecting the control to produce the moment of that kind. If the control is so connected as to increase the damping, the sign + must be taken and the equation in this case becomes

$$J\ddot{\theta} + (B + S)\dot{\theta} + C\theta = 0 \quad [2]$$

It may be seen from the form of Equation [2] that the action of the weight so controlled will merely increase the natural coefficient B of damping of the oscillating system.

However, in addition to this expected behavior, the pendulum, under certain conditions, begins to oscillate spontaneously with a much higher frequency than that corresponding to its own damped period, or to that of an externally applied disturbing moment. For example, a pendulum having a natural period of about 7 sec was found to oscillate with a period of less than 1 sec with amplitude of a fraction of a degree. This particular case will be studied in this paper as a typical case of self-excitation caused by a retarded-action phenomenon.

Hysterodifferential Equation of Motion

In the foregoing simplified treatment of the problem, it was tacitly assumed that the control system acts with an infinite rapidity, i.e., with a zero time lag. In reality, the term $S\bar{\theta}$ is a retarded quantity (in the following treatment, the bar above a symbol designates that the corresponding quantity is retarded). In the arrangement described, this means that, whereas an ideal control should introduce a lever arm x corresponding to the present instant t of motion, the real control introduces x which relates to a past instant $(t - \Delta t)$ where Δt is the time lag.

Since the angular velocity $\dot{\theta}(t)$, considered as a function of time, is a continuous function with continuous derivatives under the normal conditions (absence of impulsive forces) it can be expanded in Taylor's series

$$\bar{\dot{\theta}} = \dot{\theta} - \Delta t\ddot{\theta} + \frac{\Delta t^2}{2!}\dddot{\theta} - \frac{\Delta t^3}{3!}\theta^{IV} + \dots \quad [3]$$

Equation [3] expresses the retarded value $\bar{\dot{\theta}}$ of angular velocity in terms of nonretarded values of $\dot{\theta}$ and its higher derivatives.

Substituting $\bar{\dot{\theta}}$ into the differential equation

$$J\ddot{\theta} + B\dot{\theta} + S\bar{\dot{\theta}} + C\theta = 0 \quad [4]$$

[2] There are several ways of accomplishing this; one of the simplest consists in mounting a small constrained gyroscope on the pendulum so that it will not interfere with the motion. This gyro can control through a vacuum-tube system the speed of the motor in proportion to $\dot{\theta}$. By providing a follow-up arrangement between the excursion of the weight and the control current, the couple of the form $S\dot{\theta}$ can be produced.

Using Equation [3]

$$S\left[\dots(-1)^n\frac{\Delta t^n}{n!}\theta^{(n+1)} + \dots - \frac{\Delta t^3}{3!}\theta^{IV} + \frac{\Delta t^2}{2!}\ddot{\theta} - \Delta t\cdot\dddot{\theta} + \ddot{\theta}\right] + J\ddot{\theta} + B\dot{\theta} + C\theta = 0 \quad [5]$$

Equation [5] is a hysterodifferential equation of motion of the pendulum. It is seen that this is an equation of an infinitely high order, with absolute values of higher-order terms decreasing with the increasing order.

It is to be noted that the new equation is still linear; there appear therefore new frequencies corresponding to an infinite number of roots of its characteristic equation.

One could proceed by limiting the number of terms of the higher order to some finite number and investigating the equation in this manner. Such procedure is generally complicated and there is no certainty as to whether the effect of terms of the higher order is negligible or not.

It is preferable for that purpose to transform this equation to a different form, owing to the fact that the series of terms of a gradually increasing order is always convergent.

Asymptotic Form of the Hysterodifferential Equation

Equation [3] can be written

$$\bar{\dot{\theta}} = \dot{\theta}\left[1 - \Delta t\frac{\ddot{\theta}}{\dot{\theta}} + \frac{\Delta t^2}{2!}\frac{\dddot{\theta}}{\dot{\theta}} - \frac{\Delta t^3}{3!}\frac{\theta^{IV}}{\dot{\theta}} + \dots\right] \quad [6]$$

Since the original hysterodifferential Equation [5] is linear with constant coefficients, it is satisfied by a solution $\theta = \theta e^{zt}$ where $z = (\alpha + i\omega)$; $(i = \sqrt{-1})$.

Forming the subsequent derivatives entering into the ratios $\ddot{\theta}/\dot{\theta}$, $\dddot{\theta}/\dot{\theta}$, ..., one finds that these ratios are z, z^2, z^3 ... so that Equation [6] becomes

$$\bar{\dot{\theta}} = \dot{\theta}\left(1 - \Delta tz + \frac{\Delta t^2}{2!}z^2 - \frac{\Delta t^3}{3!}z^3 + \dots\right) = \dot{\theta}e^{-\sigma} \quad [7]$$

where $\sigma = \Delta t\cdot z = \alpha\cdot\Delta t + i\omega\cdot\Delta t = \gamma + i\varphi$, putting $\alpha\cdot\Delta t = \gamma$ and $\omega\cdot\Delta t = \varphi$.

Substituting $\bar{\dot{\theta}} = \dot{\theta}e^{-\sigma}$ into Equation [4]

$$J\ddot{\theta} + (B + Se^{-\sigma})\dot{\theta} + C\theta = 0 \quad [8]$$

This is another form of the hysterodifferential Equation [5] in which the infinite series of higher time derivatives arising from Taylor's expansion has been replaced by its sum, $Se^{-\sigma}\cdot\dot{\theta}$.

Substituting $\theta = \theta_0 e^{zt}$ into Equation [8]

$$[Jz^2 + (B + Se^{-\sigma})z + C]\theta_0 e^{zt} = 0 \quad [9]$$

In order to have solutions other than trivial ones $\theta_0 = 0$, it is necessary to equate the bracket to zero, since $e^{zt} \neq 0$; this gives

$$Jz^2 + (B + Se^{-\sigma})z + C = 0 \quad [10]$$

For self-excitation it is necessary to make $\alpha > 0$ initially. In fact, in such a case, being given a small departure θ_0 initially, the process of self-excitation will be started according to the law $\theta = \theta_0 e^{\alpha t}e^{i\omega t}$.

As regards ω, the angular frequency, it is always a positive quantity. The solution of the problem is thus reduced to that of Equation [10].

Substituting $z = (\alpha + i\omega)$

$$J(\alpha + i\omega)^2 + (B + Se^{-\gamma}e^{-i\varphi})(\alpha + i\omega) + C = 0$$

Since $e^{-i\varphi} = \cos\varphi - i\sin\varphi$, this gives rise to two equations obtained by putting separately the real and the imaginary parts equal to zero

$$\left.\begin{aligned} J(\alpha^2 - \omega^2) + B\alpha + Se^{-\gamma}(\alpha\cos\varphi + \omega\sin\varphi) + C = 0 \\ 2J\alpha\omega + B\omega + Se^{-\gamma}(\omega\cos\varphi - \alpha\sin\varphi) = 0 \end{aligned}\right\} \ldots [11]$$

Transferring terms with $Se^{-\gamma}$ on one side of Equations [11] and dividing them out (which eliminates $Se^{-\gamma}$), finally upon rearranging the terms according to the power of α

$$(J\sin\varphi)\alpha^3 + (B\sin\varphi + J\omega\cos\varphi)\alpha^2 + [(J\omega^2 + C)\sin\varphi]\alpha + \omega[(J\omega^2 - C)\cos\varphi + B\omega\sin\varphi] = 0 \ldots [12]$$

Equation [12] arranged according to the powers of ω is

$$(J\cos\varphi)\omega^3 + [(J\alpha + B)\sin\varphi]\omega^2 + [(J\alpha^2 - C)\cos\varphi]\omega + [(C + B\alpha + J\alpha^2)\alpha\sin\varphi] = 0 \ldots [13]$$

Conditions of self-excitation are fulfilled in the domain where both α and ω are real and positive.

Dividing both equations by $\cos\varphi$

$$(J\tan\varphi)\alpha^3 + (B\tan\varphi + J\omega)\alpha^2 + [(J\omega^2 + C)\tan\varphi]\alpha + \omega[(J\omega^2 - C) + B\omega\tan\varphi] = 0 \ldots [14]$$

$$J\omega^3 + [(J\alpha + B)\tan\varphi]\omega^2 + (J\alpha^2 - C)\omega + \alpha(C + B\alpha + J\alpha^2)\tan\varphi = 0 \ldots [15]$$

Zones of Self-Excitation

Taking $\tan\varphi$ as a factor in the preceding equations

$$\tan\varphi = -\frac{\omega[J\alpha^2 + (J\omega^2 - C)]}{J\alpha^3 + B\alpha^2 + (C + J\omega^2)\alpha + B\omega^2} \ldots [16]$$

Since the observed self-oscillations are generally above the synchronism $(J\omega^2 - C) > 0$ and because $\alpha > 0$, $\tan\varphi < 0$ during the transient period of self-excitation; that is $\pi/2 < \varphi < \pi$, or $3\pi/2 < \varphi < 2\pi$.

The self-excited process eventually reaches a stable condition when $\alpha = 0$. Equation [16] shows that in this case

$$\tan\varphi_0 = -\frac{J\omega^2 - C}{B\omega} \ldots [17]$$

On the basis of Equation [16], it cannot be determined whether the self-excitation is possible below the synchronism $(J\omega^2 - C) < 0$. It will be shown in the following that only the oversynchronous case of self-excitation is possible.

During the transient period when the amplitudes are still increasing $(\alpha > 0)$, $\tan\varphi > \tan\varphi_0$; this can be seen by putting $\alpha = \infty$ in Equation [16], which gives $\tan\varphi = -0$. The self-excitation starts thus in the region of $\varphi = \pi - \epsilon$ (ϵ being a small quantity) and approaches the value of φ_0 given by Equation [17] for a steady state.

An Alternative Method

Dividing Equation [14] by $\tan\varphi$

$$J\alpha^3 + (B + J\omega\operatorname{cotan}\varphi)\alpha^2 + (J\omega^2 + C)\alpha + \omega[(J\omega^2 - C)\operatorname{cotan}\varphi + B\omega] = 0 \ldots [18]$$

In this form, the first term of the equation is positive; the equation being of an odd degree in α has certainly one real root, this root is positive, as required by the condition of self-excitation if the last term is negative. Since $\omega > 0$, this condition is equivalent to

$$(J\omega^2 - C)\operatorname{cotan}\varphi + B\omega < 0$$

whence

$$\tan\varphi > -\frac{J\omega^2 - C}{B\omega}$$

Designating the absolute value of $\tan\varphi$ by $|\tan\varphi|$ this gives

$$|\tan\varphi| < \frac{J\omega^2 - C}{B\omega}$$

For a stable state of self-excitation $\alpha = 0$; in this case the last term of Equation [18] vanishes, which gives $|\tan\varphi_0| = \dfrac{J\omega^2 - C}{B\omega}$ as previously found. Therefore, the condition for an oversynchronous excitation is

$$|\tan\varphi| \leq \frac{J\omega^2 - C}{B\omega} \ldots [19]$$

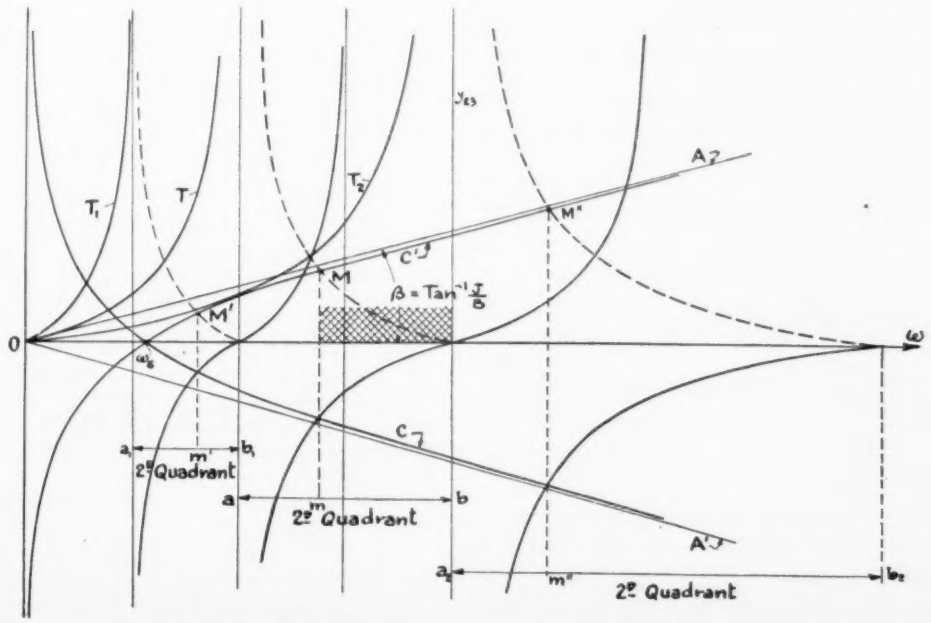

FIG. 2 GRAPHICAL REPRESENTATION OF CONDITIONS OF SELF-EXCITATION

the sign $<$ holds for the transient condition and $=$, for the steady state.

Graphic Interpretation

These conditions of self-excitation are represented graphically in Fig. 2 in which $\tan \varphi = \tan (\omega \Delta t)$ is plotted against ω as curve T. Tan φ undergoes discontinuities for $\varphi = \omega \Delta t = n\pi/2$ ($n = 1, 3, 5, \ldots$). Absolute values of tan φ are also plotted in dotted lines in even quadrants where $\tan \varphi < 0$.

Straight lines OA and OA' have angular coefficients respectively equal to $+J/B$ and $-J/B$; the curves B and B' are hyperbolas $+ C/B\omega$ and $-C/B\omega$ referred to the axes y and ω as asymptotes; these curves B, B' are omitted in Fig. 2.

By adding algebraically the ordinates of curves B and A' and those of curves B' and A, curves C and C' are obtained. Curve C has for its equation, $y_c = \dfrac{C}{B\omega} - \dfrac{J}{B}\omega = -\dfrac{J\omega^2 - C}{B\omega}$, and the equation for curve C' is

$$y_c' = -\frac{C}{B\omega} + \frac{J\omega}{B} = \frac{J\omega^2 - C}{B\omega}$$

Both curves intersect the abscissa axis at the point $\omega_s = \sqrt{C/J}$ which corresponds to the undamped synchronism of the system.

Condition of self-excitation of parasitic oscillations, given by the criterion, Equation [19], is found in the diagram, Fig. 2, between the ordinate y_{23} separating the second and the third quadrants and the abscissa of the point M, which is the intersection of curves C' and $|\tan \varphi|$. Within this range the inequality of Equation [19] is, in fact, satisfied.

The limit frequency is at the point m, the abscissa of M. The shaded area indicates the range of frequencies within which the self-excitation occurs in a transient state ($\alpha > 0$).

Vector Diagrams

The foregoing criteria show that the self-excitation above synchronism is possible in the second as well as in the fourth quadrants which means that these two oscillations may be of two different frequencies.

A further restriction to this multiplicity of possible frequencies is obtained from a consideration of conditions of dynamical equilibrium of moments applied to the dynamical system.

In view of the fact that this question resembles closely a similar question encountered in the theory of alternating currents, a parallel study of both problems is useful.

The differential equation of an electric circuit, containing an inductance L, resistance R, and capacity C, in series, and acted upon by electromotive force $E = E_0 e^{j\omega t}$ is[3]

$$L\frac{di}{dt} + Ri + \frac{1}{C}\int i\,dt = E_0 e^{j\omega t}$$

Differentiating this equation

$$L\frac{d^2i}{dt^2} + R\frac{di}{dt} + \frac{1}{C}i = E_0 j\omega e^{j\omega t} \quad \ldots\ldots\ldots [20]$$

The differential equation of a pendulum acted upon by an external moment $D = D_0 e^{j\omega t}$ is

$$J\frac{d^2\theta}{dt^2} + B\frac{d\theta}{dt} + C\theta = D_0 e^{j\omega t} \quad \ldots\ldots\ldots\ldots [21]$$

It is seen that the differential Equations [20] and [21] are identical in form, with the exception that the right side of the electrical equation figures the derivative of $E_0 e^{j\omega t}$, whereas, in the dynamical equation appears the nondifferentiated quantity $D_0 e^{j\omega t}$.

As the result of this, the real and the imaginary axes are inverted in electrical and mechanical vector diagrams. For example, the vector representing Rdi/dt is along the real axis in the electrical diagram, whereas, the vector $Bd\theta/dt$, representing an analogous physical quantity (the dissipation of energy), is along the imaginary axis in the mechanical diagram.

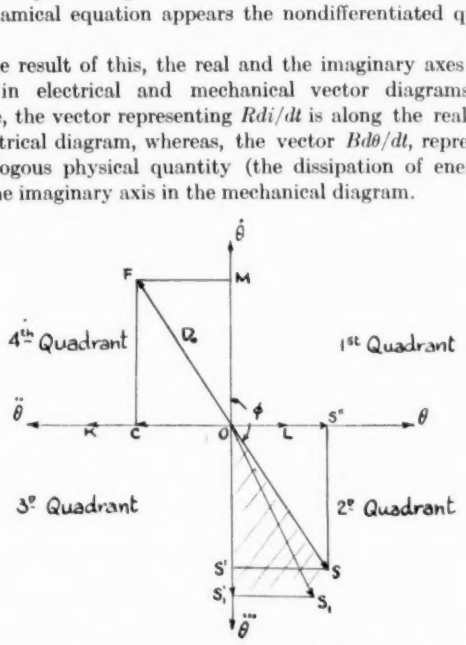

Fig. 3 Dynamical-Vector Diagram of Steady State of Self-Excitation

With this change of a formal character, the dynamical vector diagram of the steady state of self-excitation is shown in Fig. 3.

Vector $OL = C\theta_0$ is in phase with the angle θ

Vector $OM = jB\omega\theta_0$ is in phase with the angular velocity $\dot\theta$

Vector $OK = -J\omega^2\theta_0$ is in phase with the angular acceleration $\ddot\theta$

Vector $OC = OK + OL = (C - J\omega^2)\theta_0$

The vector sum $OC + CF = OC + OM = [(C - J\omega^2) + jB\omega]\theta_0$ clearly represents the left side of Equation [21] upon substituting $\theta = \theta_0 e^{j\omega t}$. Hence, OF represents the amplitude D_0 of the external moment with its phase relatively to θ.

When the self-excitation exists, the external moment D is absent. Since for dynamical equilibrium the polygon OCF is to be closed, a vector OS equal and opposite is necessary for this purpose. Thus, vector OS represents the retarded action, lagging behind the vector OM from which it is derived by an angle φ ($\pi/2 < \varphi < \pi$). This vector OS is in the second quadrant as previously found by another method. Tan φ is therefore negative and its absolute value is $|\tan \varphi| = OC/OM = \dfrac{J\omega^2 - C}{B\omega}$, as found previously, Equation [19].

The vectors in the diagram represent the moments acting on the system. If they are multiplied by ω they are capable of representing the power. It is seen from the diagram Fig. 3 that the conditions of self-excitation can be formulated as follows: (1) $OM = OS'$ and (2) $OC = OS''$.

The first condition states that the power output from the system caused by the dissipation of energy $B\dot\theta$ must be equal to the power input into the system through the component $OS' = OS \cos \varphi$ of the retarded action OS. This latter component figures therefore on the same basis as a negative-resistance effect in an electric circuit; it is well known that in an electric circuit no self-excitation is possible without a negative-resistance element's being present in the circuit.

The second condition $OC = OS''$, that is, $\theta_0(J\omega^2 - C) = OS \sin \varphi$ merely fixes the frequency of self-excitation.

Since OM is always directed along the imaginary axis upward, the vector OS' being equal and opposite to it, is always

[3] In order to avoid confusion in the following equations, j designates $\sqrt{-1}$ and i the electric current in this section on "Vector Diagrams."

directed along the same axis downward. This means that the vector OS can only be either in the second or in the third quadrant. In the first case, the self-excitation is above synchronism and in the second below it.

Thus, the retarded action OS can never be either in the first or in the fourth quadrants, if the self-excitation is to occur at all.

The condition of self-excitation previously found $|\tan \varphi| \leqslant \frac{J\omega^2 - C}{B\omega}$ has a simple significance in the vector diagram. In fact, since φ is contained between the limits $\frac{\pi}{2} < \varphi < \pi$ the previous condition means that the vector OS must be either somewhere inside the shaded area (during transient condition) or along the line OS. In the first case when it is, say, at OS_1 its projection is $OS_1' > OM$. In other words, in order to start the self-excitation, it is necessary to have the initial input of energy into the system greater than its dissipation. But as soon as the self-excitation is established, S_1 comes to S and $OS' = OM$, which corresponds to the steady state $\left(\tan \varphi = \frac{J\omega^2 - C}{B\omega}\right)$, as seen from the diagram; in such a case, the energy input through the retarded action $S\bar{\theta}$ is equal to its dissipation $B\dot{\theta}$.

Theoretically, if the self-excitation occurs in the second quadrant, it must also occur in the sixth, tenth, etc., quadrants, by adding $2\pi n$ (n being an integer). Such higher-order self-excitations correspond however to much higher frequencies and cannot be observed in practice; the only quadrant of interest from the standpoint of self-excitation is therefore the second quadrant.

Effect of Time Lag on Self-Excitation

If the time lag is made smaller, the spacing of quadrants for $\tan \varphi$ curves becomes wider for the same frequency scale on the abscissa axis (curves T_2 in Fig. 2); for larger time lags the spacing of quadrants becomes more crowded (curves T_1).

Curves C, C', and, hence, the synchronous frequency of the system remain the same, since they do not depend upon the time lag.

Time lags, assumed in the construction of Fig. 2, are half the size for the curve T_2 and twice as large for T_1, than the time lag adopted for curve T. For this latter case, the stable frequency is at the point m. For smaller time lag (curve T_2), it is at the point m'' and for a larger lag (curve T_1) it is at m'. All three points m, m', m'' are in the second quadrants of their respective frequencies (ab, a_1b_1, and a_2b_2).

Thus, it can be seen that the frequency of self-excitation decreases with an increasing time lag and vice versa. This is generally observed in practice.

Within the frequency range a_2b_2 of the second quadrant and small time lag, the self-excited frequency m'' is nearer to the point a_2 than to the point b_2. For large time lag m' approaches the end b_1 of its frequency range a_1b_1.

Thus, with a sufficiently small time lag, the point m'' may come so close to the point a_2 that the self-excitation may disappear entirely. This will happen when the vertical projection OS' of OS (Fig. 3) will become smaller than the vector OM. At this point, the energy input into the self-excitation process becomes smaller than the losses inherent in its maintenance. It is a well-known fact that systems with very small time lags behave practically in a "dead-beat" manner.

Conversely, for a large time lag, the point m' comes closer to the point b_1 in the second quadrant (Fig. 2). In the diagram Fig. 3, the vector OS representing the retarded action approaches the downward position. In such a case the conditions for the maintenance of the hunt are the most favorable. In fact, it is usually observed that a relatively low-frequency hunt, due to large time lags, is very persistent.

Effect of Fixed Parameters on Self-Excitation

If the time lag is small, the frequency of self-excitation is relatively high and the difference of ordinates of the curve C', Fig. 2, and its asymptote A is negligible. The angular coefficient of the asymptote A is J/B. The point of intersection M of the curve C' with the curve $|\tan \varphi|$ becomes practically identical with that of A with the same curve $|\tan \varphi|$.

The greater this ratio J/B, the nearer comes the frequency m to the critical value $\pi/2\Delta t$ at which the self-excitation ceases. The self-excited frequency thus decreases with an increasing inertia J and decreasing damping B.

Conversely, if this ratio decreases, the asymptote A rotates clockwise and the point M moves along the curve $|\tan \varphi|$ toward the point $\omega = \pi/\Delta t$ in the frequency range; the self-excited frequency increases in this case.

Thus, at a constant inertia, an increase of damping increases the frequency of the parasitic oscillation. In view of the fact that the amplitude of the parasitic oscillation is generally very small, it is difficult to provide an efficient damping.

As regards the parameter C, the spring constant of the system, it enters into the determination of the curve C' and not of its asymptote A. If, on the other hand, the time lag is small enough, the difference of ordinates between the curve C' and its asymptote A is negligible. This shows that the effect of C is also negligible, as compared to the other two factors, i.e., inertia J and damping B.

Effect of the Variable Parameter S on Self-Excitation

Parameter S, characterizing the intensity of self-excitation, that is, of the retarded action, does not appear in the preceding equations. This is due to the fact that Equations [11] were divided out so as to eliminate $Se^{-\gamma}$.

In order to be able to take into account the influence of this factor on self-excitation, Equation [10] must be studied directly. Since the determination of the regions in which the self-excitation is possible has been made already, the study can be simplified by putting $\alpha = 0$.

The condition for the existence of a steady self-excited oscillation is $\theta = \theta_0 e^{i\omega t}$, where i again designates $\sqrt{-1}$.

Putting $\sigma = i\omega\Delta t = i\varphi$ in Equation [8]

$$J\ddot{\theta} + (B + Se^{-i\varphi})\dot{\theta} + C\theta = 0 \quad \ldots\ldots\ldots\ldots [22]$$

Since $e^{-i\varphi} = \cos \varphi - i \sin \varphi$, this equation becomes

$$J\ddot{\theta} + (B + S\cos\varphi)\dot{\theta} - iS\sin\varphi \cdot \dot{\theta} + C\theta = 0 \quad \ldots\ldots [22a]$$

For a harmonic oscillation $\theta = \theta_0 e^{i\omega t}$, $\dot{\theta} = i\omega\theta$, whence $-i\dot{\theta} = \omega\theta$. This gives

$$J\ddot{\theta} + (B + S\cos\varphi)\dot{\theta} + (C + S\omega\sin\varphi)\theta = 0 \quad \ldots\ldots\ldots [23]$$

For a steady state of self-excitation, clearly $B + S\cos\varphi = 0$, whereas, during the transient state ($\alpha > 0$), $(B + S\cos\varphi) < 0$; thus in general $B + S\cos\varphi \leqslant 0$; that is, $\cos\varphi \leqslant -B/S$.

Since both B and S are positive, φ is in the second quadrant; as to the fourth quadrant, it is ruled out as was previously explained.

Furthermore, since $\cos\varphi < 1$, $S > B$; that is, the self-excitation of oscillations cannot occur if the coefficient of intensity of the retarded action is smaller than the coefficient B of damping.

This is obvious from a physical consideration, since $S\dot{\theta}$ and $B\dot{\theta}$ are proportional to the energy input into the system and its dissipation, respectively. Clearly, the self-excitation becomes impossible if the average energy input into the system is less than its dissipation.

For a steady state of self-excitation $J\bar{\theta} + (C + S\omega \sin \varphi)\theta = 0$ and, since $\sin \varphi = \sqrt{1 - (B/S)^2}$ this gives

$$J\bar{\theta} + (C + \omega\sqrt{S^2 - B^2})\theta = 0 \quad \ldots\ldots\ldots [24]$$

The steady frequency of self-excitation is thus given by the positive root of the quadratic equation

$$J\omega^2 - \omega\sqrt{S^2 - B^2} - C = 0$$

that is

$$\omega = \omega_1 + \sqrt{\omega_1^2 + \omega_0^2} \quad \ldots\ldots\ldots [24a]$$

where $\omega_1 = \sqrt{S^2 - B^2}/2J$ and $\omega_0 = \sqrt{C/J}$.

For $S = B$, $\omega = \omega_0$; the self-excitation cannot occur below this value for S.

Thus, no self-excitation is possible below the synchronism which rules out the possibility of self-excitation in the third quadrant.

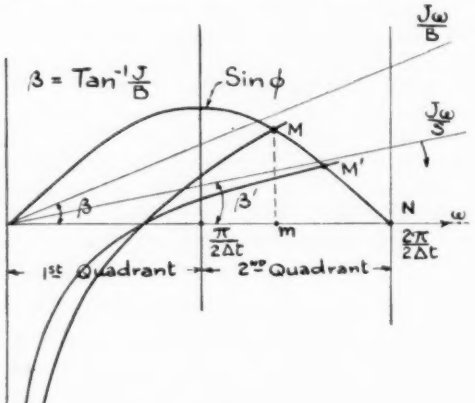

FIG. 4 GRAPHICAL CONSTRUCTION SHOWING SELF-EXCITATION RESULTING FROM INTRODUCTION OF SIN φ

The self-excitation is thus possible only in the second quadrant ($\pi/2 < \varphi < \pi$). If S is increased, Equation [24] shows that the self-excited frequency increases as long as it remains within the range in which the self-excitation is possible, as previously investigated.

In order to be able to show how the self-excited frequency changes with S, the diagram of Fig. 2 must be changed so as to introduce this factor. Arranging the first Equation [11] according to the powers of α

$$J\alpha^2 + (B + Se^{-\gamma} \cos \varphi)\alpha + [(C - J\omega^2) + Se^{-\gamma}\omega \sin \varphi] = 0$$

The condition for $\alpha \geqslant 0$ is $[(C - J\omega^2) + Se^{-\gamma}\omega \sin \varphi] < 0$; that is

$$\sin \varphi \leqslant \frac{J\omega^2 - C}{\omega} \frac{1}{Se^{-\gamma}} \quad \ldots\ldots\ldots [25]$$

From the second Equation [11]

$$\alpha = -\frac{\omega[B + Se^{-\gamma} \cos \varphi]}{2J\omega - Se^{-\gamma} \sin \varphi} \quad \ldots\ldots\ldots [26]$$

Since $B + Se^{-\gamma} \cos \varphi \leqslant 0$, from Equation [26] for $\alpha > 0$, it follows that $2J\omega - Se^{-\gamma} \sin \varphi \geqslant 0$, that is

$$\sin \varphi \leqslant \frac{2J\omega^2}{\omega Se^{-\gamma}} \quad \ldots\ldots\ldots [27]$$

Comparing inequalities of Equations [25] and [27], it is observed that the first dominates the second, because if the first is satisfied, the second is satisfied eo ipso; hence, only the inequality, Equation [25], is of interest.

For a steady state $e^{-\gamma} = 1$ and we have

$$\sin \varphi = \frac{J\omega^2 - C}{S\omega} \text{ and } \cos \varphi = -\frac{B}{S} = -\frac{B\omega}{S\omega}$$

Thus, it is seen that, although both $\sin \varphi$ and $\cos \varphi$ depend upon S, this factor was eliminated in the expression for $\tan \varphi$, with which the previous formulas were established.

If now $\sin \varphi$ is introduced into the graphical construction of Fig. 4, instead of $\tan \varphi$, this dependence upon S will appear. This is shown in Fig. 4.

The essential difference between the two diagrams is in the fact that the angular coefficient of the asymptote is now J/S (S being a variable quantity) and not J/B as it was in the case of Fig. 2. The limit frequency is reached as soon as S reaches the value B. The point M represents this limiting frequency m. It is obtained by the intersection of curves $\sin \varphi$ and $\dfrac{J\omega^2 - C}{B\omega}$.

If S is increased, the representative point comes to M' (intersection of curves $\sin \varphi$ and $\dfrac{J\omega^2 - C}{S\omega}$, with $S > B$). With S increasing, the asymptote turns in the direction of the arrow and the stable frequency approaches the limit N at which the self-excitation disappears.

In fact, it is generally observed that, for a sufficiently intense coupling S, the parasitic oscillations disappear and the system becomes "dead beat."

GENERALIZATION

Although the preceding study relates to a rather particular case of self-excitation, a further generalization of this theory does not present any difficulties.

It must be noted that, in establishing the preceding relations, a number of simplifying hypotheses were tacitly assumed:

1 The retarded moment is a linear function of the corresponding parameter. For example, in the analysis, this function was simply $S\bar{\theta}$, where S is a constant.

2 The dynamical system is governed by a linear differential equation with constant coefficients.

3 Time lag Δt is constant.

The first condition means that the retarded moment reproduces the retarded element of motion $(\bar{\theta}, \dot{\bar{\theta}}, \ddot{\bar{\theta}})$ without any distortion.

The second condition permits of applying the principle of superposition of component motions arising from the infinity of roots of the characteristic equation of the original Equation [5]. This, in turn, permits reducing that equation to its asymptotic form Equation [8], since the original equation is satisfied by the solution of the form $\theta_0 e^{zt}$ under such circumstances.

The last condition merely specifies the definiteness of Taylor's expansion, introduced into the problem.

These conditions introduce a certain idealization of real problems. By waiving them, the problems become more complicated, or even impossible to solve.

On the other hand, as was mentioned on several occasions, the conclusions derived from such an idealized formulation of the problem, seem to be in a fairly good agreement with the observed facts.

It is possible, under such assumptions, to extend the preceding theory to a greater variety of cases, by introducing the retarded moment $S_1\bar{\theta}^k$ into the original differential Equation [1']. The index k in this notation refers to the order of the corresponding derivative; the retarded moment previously investigated in accordance with this notation is $S_1\bar{\theta}$, in so far as it is obtained from the first derivative.

It is possible, in this manner, to investigate the effect of other retarded couples, such as $S_0\bar{\theta}$ (retarded angle), $S_2\bar{\ddot{\theta}}$ (retarded acceleration), etc., which may appear in different problems.

The following hysterodifferential equations are written in the asymptotic form:

$$J\ddot{\theta} + B\dot{\theta} + (C + S_0\epsilon^{-\sigma})\theta = 0 \quad \text{[I]}$$

$$J\ddot{\theta} + (B + S_1\epsilon^{-\sigma})\dot{\theta} + C\theta = 0 \quad \text{[II]}$$

$$(J + S_2\epsilon^{-\sigma})\ddot{\theta} + B\dot{\theta} + C\theta = 0 \quad \text{[III]}$$

$$S_2\epsilon^{-\sigma}\ddot{\theta} + J\ddot{\theta} + B\dot{\theta} + C\theta = 0 \quad \text{[IV]}$$

Equation [II] was studied in detail in the preceding sections. Equation [I] is obtained, if the moment of the weight w in the dynamical model, shown in Fig. 1, is so timed as to be in phase with the angle θ. In Equation [III] this timing must be in phase with $\ddot{\theta}$ and, in Equation [IV], in phase with $\bar{\theta}$, and so on.

In all these cases, as well as in combinations of such cases, the procedure is the same as that previously explained in connection with Equation [II]:

1 To substitute a solution $\theta = \theta_0\epsilon^{zt}$ which leads to the characteristic equation in asymptotic form, Equation [8].

2 To expand the characteristic equation by substituting $z = \alpha + i\omega$. In this manner, by equating separately the real and the imaginary parts to zero, two equations are obtained.

3 By eliminating $S\epsilon^{-\sigma}$ between these two equations one equation is obtained which is arranged according to the powers of α. These equations are of a gradually increasing order in terms of α, e.g., quadratic for Equation [I], cubic for Equation [II], quartic for Equation [III], etc.

4 The next step is to establish the conditions for existence of at least one positive real root for α, which determines the zones within which the self-excitation is possible.

5 The limit of self-excitation is obtained by putting $\alpha = 0$ in the equation for α.

The angle φ, obtained in this manner, always designates the lag of the retarded quantity with respect to the quantity from which it derives.

The interesting feature obtained from a comparison of different hysterodifferential Equations [I] to [IV] is that, in the vector diagram, the retarded vector $S_k\theta^k$ is always in the second quadrant as specified in Fig. 3. This is due to the fact that the vector diagram imposes two additional conditions for self-excitation, i.e., the energy input into the system must be equal to its dissipation and the self-excited frequency is always above synchronism.

It was shown in connection with Equation [II], in which the retarded moment is of the form $S_1\bar{\dot{\theta}}$, this angle φ_1 is contained between the limits $\pi/2 < \varphi_1 < \pi$, which brings the retarded vector in the second quadrant.

On the other hand, if a similar calculation is reproduced in connection with Equation [I], it is found that $0 < \varphi_0 < \pi/2$; but, since θ lags by $\pi/2$ behind $\dot{\theta}$, the retarded vector $S_0\bar{\theta}$ in this case is still in the second quadrant.

Thus the following important conclusions are reached:

1 The self-excitation can appear in any case, whether the retarded action is introduced through $\bar{\theta}$, $\bar{\dot{\theta}}$, or $\bar{\ddot{\theta}}$, etc. But, once it is established, the retarded vector (either $S_0\bar{\theta}$ or $S_1\bar{\dot{\theta}}$, or $S_2\bar{\ddot{\theta}}$) must be necessarily in the second quadrant, Fig. 3. This requires that the self-excitation must occur with such a frequency as will give $0 < \varphi < \pi/2$ in the first case ($S_0\bar{\theta}$), or $\pi/2 < \varphi_1 < \pi$ in the second case ($S_1\bar{\dot{\theta}}$), or $\pi < \varphi_2 < 3\pi/2$ in the third case ($S_2\bar{\ddot{\theta}}$), etc.

In other words the relative phase angle φ between the retarded and nonretarded quantities constitutes an additional degree of freedom of the phenomenon, by which the retarded vector $S_k\bar{\theta}^k$ can maintain itself in the second quadrant as required by the condition of the balance of energy, by which the energy input into the system is equal to its dissipation.

2 From a formal standpoint, the hysterodifferential equations are characterized by the fact that at least one of their coefficients is complex. The reduction of this coefficient to the real quantities introduces additional terms in the coefficient of the next order (higher or lower) and this gives the conditions of self-excitation analytically.

3 There exist an infinite number of frequencies of self-excitation forming a discrete spectrum, corresponding to the infinity of roots of the characteristic equation. In practice, generally only one first frequency is observed if the time lag is small enough, the other frequencies cannot be observed on account of the smallness of their amplitudes.

Conclusion

Although the preceding analysis was made in connection with a pendulum of a particular type, the results obtained are quite general.

In fact, in all control systems (dynamical, electrodynamical, electrical, hydraulic, thermal, etc.), there always exists a time lag Δt in the cyclic process of their operation. A mathematical description of such a process in terms of a hysterodifferential equation simplifies the commonly established procedure of introducing "couplings" between the different parts of the system which generally lead to ordinary differential equations of a relatively high order; this usually involves considerable difficulties if one attempts to discuss the characteristic equation algebraically. Furthermore, the nature of coupling very frequently remains unknown, particularly in dynamical problems.

On the other hand, in establishing a hysterodifferential equation of a retarded control, one must know only the over-all time lag Δt, without the necessity of knowing the intermediate links in the system. Whenever this time lag is known, the application of the foregoing method is very simple.

Conversely, in a given system in which self-excited parasitic oscillations are observed, it is possible to determine the time lag from the frequency of oscillations and known parameters of the system.

It can also be shown that the self-excitation of electric oscillations (e.g., thermionic-vacuum-tube generator) can be reduced to a retarded-action phenomenon, that is, it can be expressed in terms of a hysterodifferential equation. The only difference in the case of mechanical oscillations studied is in the fact that the phase angle φ, governing the condition of self-excitation in the electrical problem, is determined by the parameters of the electric circuit (L, C, R, M) and not by the time lag Δt directly. The criteria of self-excitation are practically the same in both cases.

It is possible that the condition of self-excitation of oscillations both in electrical and mechanical systems can be better generalized on the basis of retarded-action effect common to both problems than by studying each problem, so to speak, in its own plane.

The benefit of analogies between similar problems of different engineering professions is too well known to need any additional emphasis here.

Torsion of Multiconnected Thin-Walled Cylinders

By F. M. BARON,[1] NEW HAVEN, CONN.

The author develops an arithmetical procedure for the analysis of problems of torsion. The method of analysis presented is one of successive approximations. The solution to a problem is guessed at and successively corrected until the controlling conditions of static equilibrium and of continuity of deformation are satisfied. The convergence is reasonably rapid but may be hastened with a little judicious guessing. The problem under immediate discussion is a straight hollow member with constant cross section subject to a torque about the longitudinal axis of the member. Other applications and extensions of the method presented are suggested at the end of the paper. The arithmetical procedure is illustrated by an example.

Introduction

THE problem of torsion of multiconnected thin-walled cylinders may occur in the design of structural or machine members, but particularly in the design of frames of ships, floating dry docks, and airplane wings.

It is usually desired to determine the magnitude of the stresses on a cross section and, perhaps, the angle of twist per unit of length of the member. If the total torque and the distribution of stresses on the cross section are known, the magnitude of the stresses may be computed by arithmetic. The distribution of the stresses is controlled by the conditions of static equilibrium and of continuity of deformation. The two sets of conditions are interrelated through the defined properties of the material. The problem, then, is to determine the distribution of the stresses on a cross section.

In general, the analysis of complicated members by the use of stress functions or by formal algebraic procedures is either difficult or inconvenient. There are limitations and objections to the use of models in studying the problem.

H. M. Westergaard has suggested[2] that an arithmetical procedure may be developed for analyzing problems of torsion. The arithmetical procedure presented here is similar to that developed by Hardy Cross for the analysis of flow in networks of conduits.[3]

Conditions of Static Equilibrium and of Continuity

The properties of the member dealt with in the present and succeeding sections will now be defined. The member is shown in Fig. 1.

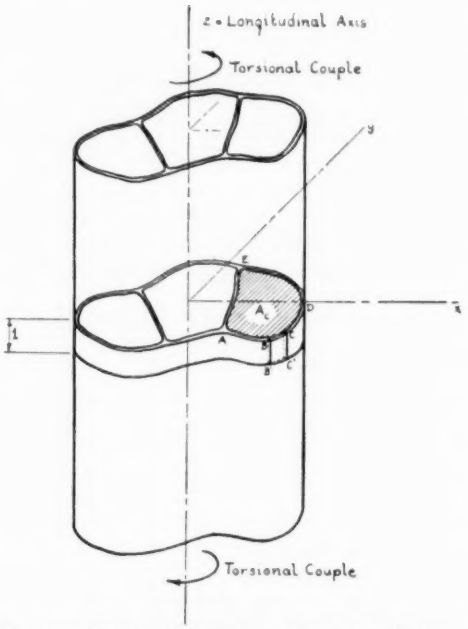

Fig. 1 Straight Hollow Member of Constant Cross Section Subject to a Torque About Its Longitudinal Axis

1 The member is straight, of constant cross section, and of homogeneous, elastic, isotropic material.

2 All the elements of a cross section rotate through the same angle. The angle is proportional to the longitudinal co-ordinate of the cross section and the constant α measuring the angle of twist per unit of length.

3 The displacement of any element of any cross section in the direction of the longitudinal axis is a function of the transverse co-ordinates only.

4 The member is hollow with walls so thin in proportion to the important transverse dimension that the shearing stresses may be assumed uniformly distributed across the thicknesses of the walls.

It is recognized that this paper does not discuss the instability of exceedingly thin walls, nor the problem of torsion when plane sections remain plane after deformation. The ordinary theory of torsion as presented first by Barré de Saint Venant is based on assumptions 1, 2, and 3. The derivations of the fundamental equations of the theory are available in a number of places in the literature.[4] It is sufficient here to summarize the relations necessary for the present work.

Consider a horizontal slice through the member shown in Fig. 1. Let the height of the slice be one unit, this unit being assumed small. Let a total force f be transferred across the thickness t of the wall at section B. The unit shear at section B is the force f divided by the thickness t. The equilibrium conditions of the element $BB'CC'$ require a total force f to be transferred across

the thickness of the wall at section C. Then, at any junction of walls, the condition of static equilibrium requires that the quantity of force f "flowing" into a junction must equal the quantity of force f "flowing" away from a junction.

Continuity of the deformations along a closed path such as $ADEA$ requires that the algebraic sum along the closed path of the relative displacements in the direction of the longitudinal axis must be zero. This requirement plus assumptions 1, 2, and 3 lead to Bredt's formula

$$\oint \frac{f}{t}\,dL = 2G\alpha A_c$$

that is, the product of the constant $2G\alpha$ and the area A_c within a closed circuit must equal the algebraic sum of the products of the unit shears $\frac{f}{t}$ and the increments of length along the closed circuit.[4] The constant G is the modulus of elasticity in shear.

Analysis of Torsion by Successive Approximations

The method of analysis presented here is a method of successive approximations. The solution to a problem is guessed at and approximately corrected. The revised answer is treated as a new guess and successively corrected until a reasonable degree of precision is obtained. The convergence is reasonably rapid and the method is useful. With some experience and judicious guessing, the convergence may be speeded up.

The method of analysis proposed always satisfies the condition of statics and successively corrects the errors in continuity of deformation until the condition of continuity is also satisfied. Other orders of procedure have been tried by the author but the foregoing is recommended for its simplicity.

The order of computations made in the method of successive approximations is as follows:

1 Assume a distribution of forces f along the walls satisfying the condition of statics.

2 Compute the following:

(*a*) The area A_c within each elementary closed circuit.

(*b*) The quantity $\frac{\text{Length } L}{\text{Thickness } t}$ for each wall.

(*c*) The quantity $\frac{1}{\Sigma L/t}$ for each elementary closed circuit.

3 Compute the algebraic sum $\Sigma f\frac{L}{t}$ for each closed circuit with due attention to the circulation ↻ or ↺ of the forces in the circuit.

4 Choose a constant $2G\alpha$ for the section, making the product of $2G\alpha$ and the area A_c within each elementary closed circuit approximately equal to the quantity $\Sigma f\frac{L}{t}$ of the circuit.

5 For each closed circuit, compute the correction $\Delta\Sigma f\frac{L}{t}$ needed to make the resultant quantity $\Sigma f\frac{L}{t}$ equal to $2G\alpha A_c$.

6 For each wall of each closed circuit multiply the corrections $\Delta\Sigma f\frac{L}{t}$ by the corresponding factors $\frac{1}{\Sigma\frac{L}{t}}$ of the circuits. Write the result Δf by the wall with due attention to the circulation of the correcting forces.

7 Compute the revised forces.

Treat the revised forces as new guesses and repeat steps 3, 5, 6, and 7 to any desired precision.

The method proposed has the advantage in that errors are not cumulative and, if made, are ultimately eliminated. It has also the desirable characteristic that an approximation to the relative distribution of forces is quickly seen.

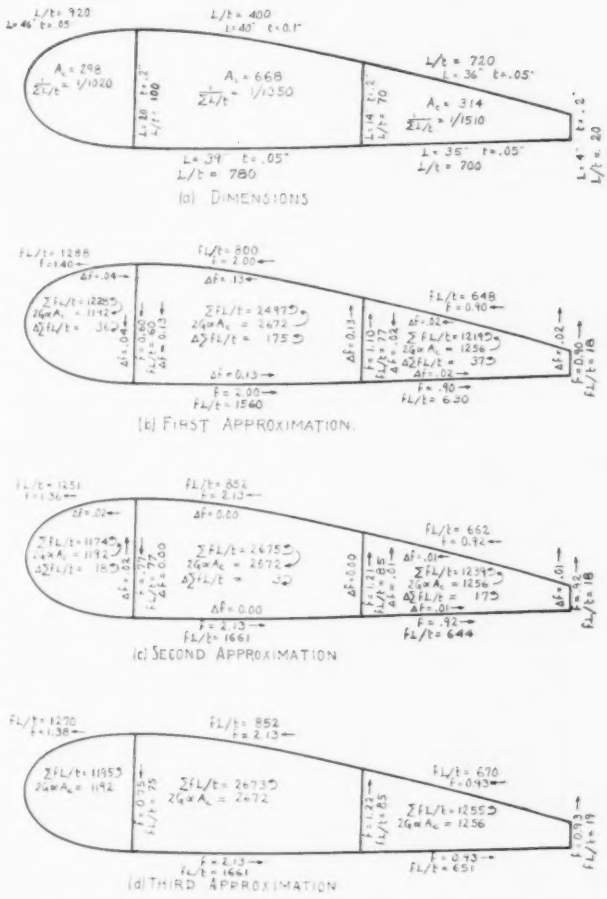

FIG. 2 COMPUTATIONS FOR SUCCESSIVE APPROXIMATIONS

The computations may be shortened by making the procedure one of successive corrections instead of successive approximations. Instead of computing the revised forces after each correction, it may be expedient to "carry over" the excessive or deficient circulation from the adjacent closed circuits. For the procedure of successive corrections, the first five computations are identical to those outlined for successive approximations. The succeeding computations are then as follows:

6 Compute the quantity $\frac{L/t}{\Sigma L/t}$ for each wall of each closed circuit.

7 For each wall of each closed circuit multiply the correction $\Delta\Sigma fL/t$ by the factor $\frac{L/t}{\Sigma L/t}$ of the wall. Write the result $\Delta fL/t$ by the wall with due attention to the circulation of the correcting flow.

8 For each closed circuit compute only the circulation "carried over" from the adjacent closed circuits. Distribute an equal but opposite circulation to each wall of the circuit according to the multiplier $\frac{L/t}{\Sigma L/t}$ of the wall. Repeat the procedure to any desired precision.

9 To compute the total correction force Δf in each wall, add up the total amount of $\Delta fL/t$ in the wall and multiply by t/L of the wall.

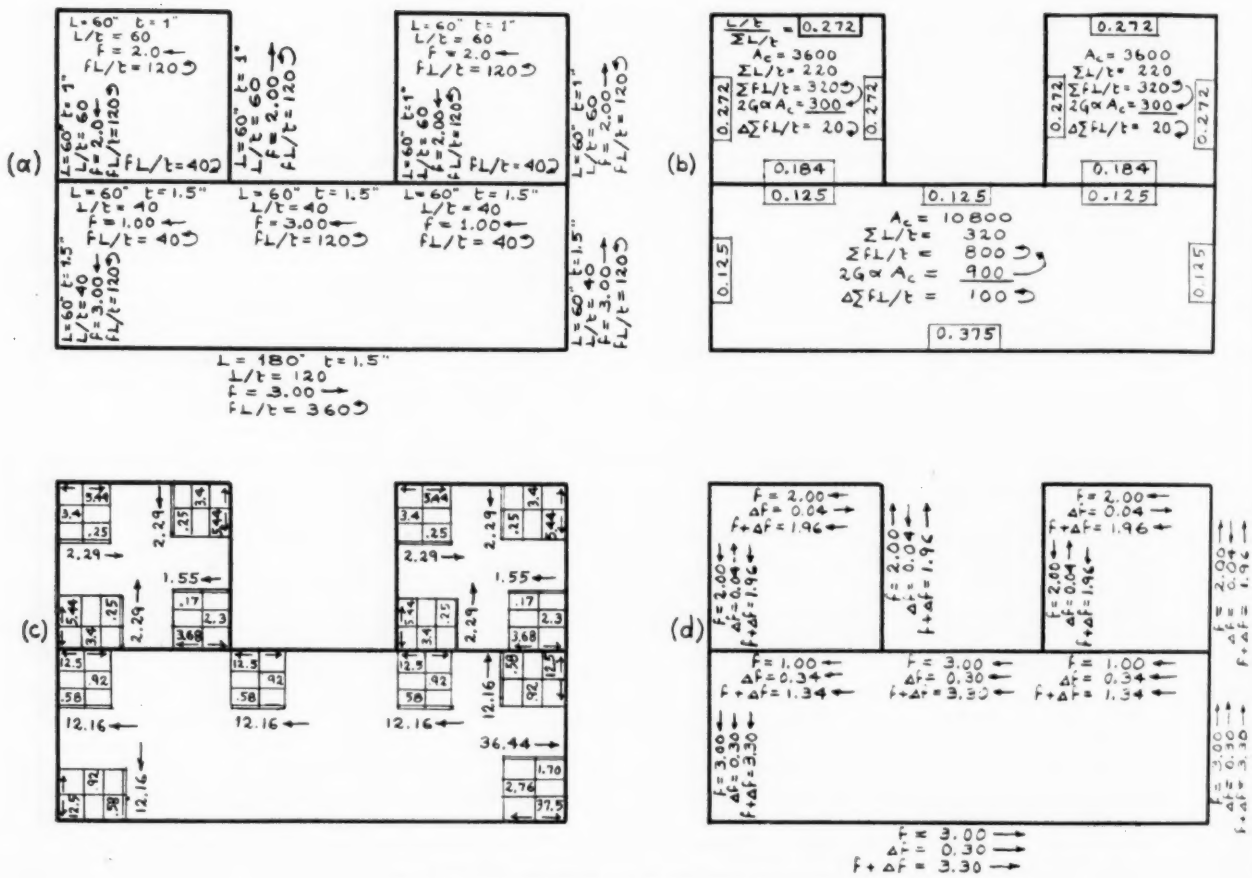

FIG. 3 COMPUTATIONS FOR SUCCESSIVE CORRECTIONS

The arrangements of computations suggested for the procedures outlined are illustrated in Figs. 2 and 3, respectively. Along each wall write the quantity L/t, the assumed force f with its direction, and the value fL/t with its direction. Write the quantity $\Sigma L/t$ inside each elementary closed circuit, and the quantities $\frac{L/t}{\Sigma L/t}$ of each wall along the wall and inside the circuit considered. Write in each elementary circuit the value of the area A_e, the value $\Sigma fL/t$ with its circulation ↻ or ↺, and the selected value of $2G\alpha A_e$. Put a curved arrow pointing to the smaller of the last two values. The arrow will show the circulation of the first correction $\Delta\Sigma fL/t$. The difference between the values of $\Sigma fL/t$ and $2G\alpha A_e$ is the magnitude of the first correction $\Delta\Sigma fL/t$. For the procedure of successive corrections, with due attention to the circulation of the corrections, write in columns perpendicular to each wall and inside each circuit the products of the corrections $\Delta\Sigma fL/t$ and the factor $\frac{L/t}{\Sigma L/t}$ of the wall.

CONCLUSIONS

The solution of the problem is correct when the conditions of static equilibrium and of continuity are satisfied. The convergence is apparently rapid but may be improved with a little judicious guessing. It is possible to get any reasonable degree of precision but, if a greater degree is wanted, considerable increase in computation is required. The method of successive approximations is recommended for its simplicity, rapidity of convergence, and generality. The answers to some problems of torsion may be obtained by successive guesses instead of successive approximations. Obviously the technique used in recording the computations depends upon the particular problem. The order and arrangements of computations may be simplified in cases of members with simple cross sections.

This paper deals directly only with straight hollow members with constant cross section. Members with a solid cross section may be studied by dividing the section into a network or grid. Clearly the related problems of fluid flow, current flow, membranes, and stress functions may be solved in the same way.

A Simple Air Ejector

By J. H. KEENAN[1] and E. P. NEUMANN,[2] CAMBRIDGE, MASS.

This paper reports the results of an investigation in which the authors studied the performance of the simplest form of ejector which would function in a useful manner. An attempt was made to analyze the data as nearly independent of other work on ejectors as possible, and to compare the performance with that predicted analytically. The primary purpose of the study was to test the utility and validity of a method of analysis, and not to devise a new type of ejector.

Previous Studies

THE many analyses that appear in the literature of ejectors may be classified into three groups: (*a*) Those that analyze only the essentially reversible processes at the entrance to and the exit from the mixing tube; (*b*) those that simplify the mixing process by assuming it to occur at constant pressure; and (*c*) those that simplify the mixing process by assuming it to occur at constant cross-sectional area.

Type (*a*) is too conventional to justify citing references. Type (*b*) is well exemplified by the work of Stodola[3] and of Bosnjakovíc.[4] The latter shows that if wall friction is neglected, the maximum ratio of secondary flow to primary flow is obtained if the mixing occurs at zero pressure. Of course, when wall friction is considered there will result a best pressure for mixing for any one apparatus.

It appears that the type (*c*) analysis has been published only by Flügel.[5] In fact, Flügel generalized his analysis so that mixing could take place partly at constant pressure and partly at constant cross-sectional area. He concluded, however, that it was best to have all mixing occur at constant area. He compares his analytical results based on this assumption with experimental data for a single ejector and finds excellent agreement. The agreement is to a minor degree the result of judicious selection of values for empirical coefficients in his analysis, but it is nevertheless striking.

Object of Present Investigation

The object of the investigation reported in this paper, was to select the simplest form of ejector which would perform in useful fashion, to analyze its performance as nearly independently of data on ejectors as possible, and to compare the actual performance with that predicted analytically. The objective is not to devise an ejector which is new or excellent, but rather to test the utility and the validity of a method of analysis.

The ejector chosen consists of a cylindrical tube (the mixing tube) with a rounded converging entrance, Fig. 1. A nozzle, which is fed with fluid at high pressure, discharges into the entrance to this tube. The stream for this nozzle entrains fluid in the tube and causes a secondary flow from a supply chamber surrounding the nozzle. The primary and secondary streams mix and issue from the tube into the atmosphere.

A better ejector can be devised by attaching a diffuser to the exit end of the mixing tube. However, since this device introduces a new independent variable (namely, the pressure at the exit of the mixing tube), it was not employed. It is hoped that analysis and experiments for an ejector with a diffuser can be presented later.

Reasons for Mixing at Constant Area

The design of the ejector is such that, when the primary nozzle discharges into the throat of the secondary nozzle, mixing of the two streams occurs at constant total cross-sectional area, Fig. 1. In the analysis, results of which are compared with experiment in the various figures, it is assumed that all mixing occurs at

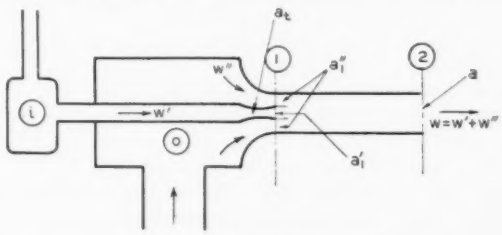

Fig. 1 The Simple Ejector

constant cross-sectional area. The reasons for this emphasis on mixing at constant area are as follows:

1 An ejector of this type can pump secondary fluid into an exhaust space at a pressure, p_2, higher than the pressure in the secondary chamber, p_0. If mixing occurs at constant pressure instead of at constant area, the pressure at the exit of the mixing tube cannot exceed the pressure in the secondary supply chamber. This means that in the absence of a diffuser a constant-pressure type of ejector can serve only as a blower and not as a pump.

2 Even when the ejector is serving as a blower, i.e., delivering air at the pressure of the secondary supply chamber, constant-area mixing gives higher secondary flows for a given exit area than constant-pressure mixing. Indeed, as shown by Fig. 2,[6] constant-area mixing gives higher secondary flows than any combination of constant-area and constant-pressure mixing.

Exception can be taken to these last two statements only at very small ratios of the area of the mixing tube to the area of the primary nozzle. Further consideration of small area ratios is given in the Appendix and in Fig. 18.

Analysis

Assume (*a*) that the primary fluid expands reversibly and adiabatically from a chamber *i* (Fig. 1) where its velocity is zero to a section 1 where it issues from the primary nozzle. This sec-

[6] See Appendix for the analysis on which Fig. 2 is based.

tion 1 is also the entrance to the mixing tube. Using subscripts to denote the locations indicated in Fig. 1, we may write

$$V_1' = \sqrt{2gRT_i \frac{k}{k-1}\left[1 - \left(\frac{p_1}{p_i}\right)^{\frac{k-1}{k}}\right]} \quad \ldots\ldots [1]$$

and

$$a_1' = \frac{w'v_1'}{V_1'} = \frac{w'v_i'}{V_1'}\left(\frac{p_i}{p_1}\right)^{\frac{1}{k}} \quad \ldots\ldots [2]$$

where V denotes velocity, T temperature, R the gas constant, k the isentropic exponent, a the cross-sectional area of the stream,

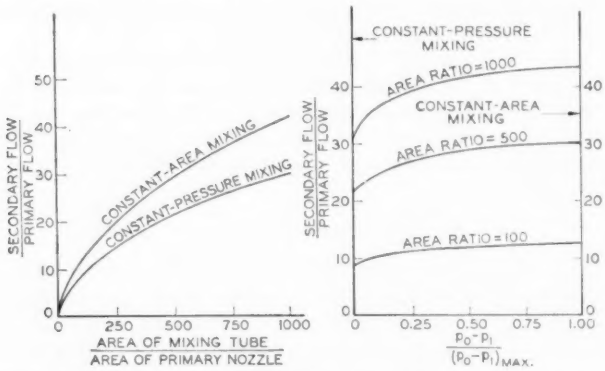

FIG. 2 PERFORMANCE OF EJECTOR FOR VARIOUS DEGREES OF MIXING AT CONSTANT PRESSURE
(The fluid is assumed incompressible. For analysis see Appendix.)

v the specific volume, and g the acceleration given to unit mass (the pound) by unit force (the pound). The superscript $'$ is used here to refer to the primary stream and the superscript $''$ is used later to refer to the secondary stream.

Assume (*b*) that the secondary fluid expands reversibly and adiabatically from a chamber 0 where its velocity is zero to the section 1 at the entrance to the mixing tube. Then we may write

$$V_1'' = \sqrt{2gRT_0 \frac{k}{k-1}\left[1 - \left(\frac{p_1}{p_0}\right)^{\frac{k-1}{k}}\right]} \quad \ldots\ldots [3]$$

and

$$a_1'' = \frac{w''v_1''}{V_1''} = \frac{w''v_0}{V_1''}\left(\frac{(p_0)}{(p_1)}\right)^{\frac{1}{k}} \quad \ldots\ldots [4]$$

Assume (*c*) that the primary and secondary streams mix as they pass adiabatically through a tube of constant area. The streams enter this tube at section 1 and leave at uniform velocity at section 2. It is assumed that the frictional forces applied by the stream on the walls of the tube are negligible. Nevertheless the process is highly irreversible because the condition of uniform velocity at 2 can only be realized through irreversible mixing of the two streams.

For the process 1–2, we may write the continuity equation

$$w = w' + w'' \quad \ldots\ldots [5]$$

the momentum equation

$$\frac{w'}{g}V_1' + \frac{w''}{g}V_1'' + p_1 a = \frac{w}{g}V_2 + p_2 a \quad \ldots\ldots [6]$$

and the energy equation

$$w'h_i + w''h_0 = w\left(h_2 + \frac{V_2^2}{2g}\right) \quad \ldots\ldots [7]$$

where w and a denote, respectively, the flow and the cross-sectional area at section 2, and h denotes enthalpy per unit mass of fluid.

We shall assume that the initial temperatures of the two streams are identical, that is, $T_i = T_0$. It follows that $h_i = h_0$. By virtue of this relation and Equation [5], Equation [7] becomes $h_i = h_2 + \frac{V_2^2}{2g}$. Noting that the change in enthalpy is equal to the specific heat multiplied by the change in temperature and that the velocity V_2 may be expressed in terms of the flow, area, and specific volume at 2, we get

$$c_p T_i = \frac{k}{k-1}p_2 v_2 + \left(\frac{w}{a_2}\right)^2 \frac{v_2^2}{2g} \quad \ldots\ldots [8]$$

This is a relation between v_2 and w/a_2 for given values of T_i and p_2.

METHOD OF SOLUTION

The method of solving the foregoing equations is one of successive approximations. First, let the throat area of the primary nozzle, a_i, be unity. Then select values for a, T_i, p_i, p_0, and p_2. For these selected values we must find the magnitudes of p_1 and w''/w'. We proceed as follows: Compute w' from the usual expression for isentropic flow through a throat of unit area from given initial conditions. Assume a value for p_1, compute V_1' from Equation [1], a_1' from Equation [2], and V_1'' from Equation [3]. Then $a_1'' = a - a_1'$ and w'' may be found from Equation [4]. Next compute w from Equation [5] and calculate w/a. Using this latter value in Equation [8], we may solve for v_2. Now we find a value for V_2 from $V_2 = \frac{wv_2}{a}$. Thus we have values for all the quantities in Equation [6]. If Equation [6] is not satisfied, a new value for p_1 is assumed, and the procedure outlined is repeated. By this method the calculated curves of Figs. 9, 11, 12, 13, 14, and 15 were found.

EXPERIMENTAL APPARATUS

The arrangement of the experimental apparatus is shown in Fig. 3. The primary stream of air passes through a strainer and

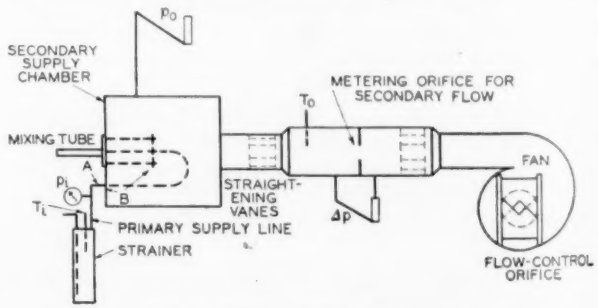

FIG. 3 EXPERIMENTAL APPARATUS

the tube A on its way to the primary nozzle at the entrance to the mixing tube. The initial pressure of the primary stream p_i is measured by a Bourdon-tube gage. The effect of friction between the gage and the nozzle was negligible except, perhaps, for the largest nozzle.

The secondary stream enters the mixing tube from a large chamber, which is supplied with air by a fan. The pressure in the chamber is controlled by means of a variable orifice at the entrance to the fan. A sharp-edged orifice is provided for measuring the secondary flow. The pressure drop across the orifice is measured by an inclined water manometer. Straightening vanes precede and follow the metering orifice.

The position of the primary nozzle relative to the entrance to the mixing tube is varied by moving the tube A in and out through guides B.

Details of the mixing tube are shown in Fig. 4. The converging entrance is $1^{5}/_{16}$ in. long. This part of the passage is referred to hereafter as the "secondary nozzle." The "throat" of the secondary nozzle is the cross section at the downstream end of the convergence. It is also the entrance to the parallel (constant-area) portion of the mixing tube. The pressure in the throat was measured at the pressure tap shown in Fig. 4. The length of the mixing tube was varied by attaching extensions as indicated.

Details of the primary nozzles are shown in Fig. 5. The nozzles

used in the earlier tests were blunt-ended with thick walls. A nozzle with the same size throat as the largest of these (0.125 in. diam) was made with thin walls tapered toward the outlet to cause as little interference as possible with the secondary stream. No difference was found between the performance of the blunt nozzle and that of the tapered nozzle. Nevertheless, all subsequent tests were made with tapered nozzles.

Only one converging-diverging nozzle was used. Converging nozzles were used in general, because a single nozzle could be used over a wide range of initial pressures of the primary stream. However, the analysis was based on the assumption that the primary nozzle was always of the proper ratio of exit area to throat area. The tests with the single converging-diverging nozzle show distinctly better agreement with the analysis.

MEASUREMENT OF FLOWS

The secondary flow was measured by means of the metering orifice shown in Fig. 3. Coefficients for this orifice were obtained from A.S.M.E. data.[7]

The primary nozzles were calibrated by means of a gasometer. Each primary nozzle was then used as the metering nozzle for its own flow.

The flow through the primary nozzle was calculated from the usual expression for isentropic flow, namely

$$0.531\, a_t \frac{p_i}{\sqrt{T_i}}$$

where a_t denotes the throat area of the nozzle. This area was at first found from measurements of the diameter of the nozzle throat. After calibrations were made, the magnitude of a_t was altered for two nozzles, in order to bring the calculated flow into agreement with the flow as measured by the gasometer. For the other four nozzles, the change indicated was so small that it could be neglected. Table 1 shows for each nozzle the diameter as measured directly, the effective diameter as found from measurements with the gasometer, and the diameter employed to calculate primary flows. It is probable that the uncertainty in the flows is about ±1 per cent. The flow ratio is uncertain to slightly more than 1 per cent.

RESULTS OF EXPERIMENTS

Tests were made to determine the effect of variation in the position of the nozzle exit relative to the throat of the secondary nozzle. The pressure rise across the mixing tube ($p_2 - p_0$) was zero for these tests.

Fig. 6, showing the flow ratio plotted against the position of the

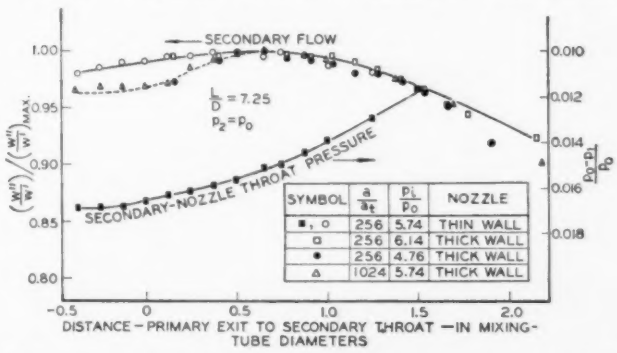

FIG. 6 EFFECT OF POSITION OF PRIMARY NOZZLE ON THROAT PRESSURE AND FLOW RATES

nozzle exit, indicates that the highest flow ratio is attained when the nozzle exit is slightly more than one half a mixing-tube diameter upstream from the throat of the secondary nozzle. The analysis given in the Appendix demonstrates that the best position for the nozzle exit is in the throat of the secondary nozzle. Some discrepancy from the analytical result is to be expected in view of the assumptions that the nozzle is properly diverged, that the secondary flow experiences no friction on the surfaces with which it comes in contact, and that the plane of the secondary-nozzle throat is one of uniform pressure. However, it should be noted that, if the exit of the primary nozzle is placed in the throat of the secondary nozzle, the flow ratio is only 1 to 3 per cent less than the maximum value.

[7] "Fluid Meters, Their Theory and Application," fourth edition, Trans. A.S.M.E., vol. 59, 1937.

The experimental data of Fig. 6 show that the best position of the primary nozzle is independent of the ratio (p_i/p_0) of the two initial pressures. Moreover, it is the same for an area ratio of 256 as for an area ratio of 1024.

In Fig. 6 is shown the variation of pressure in the throat of the secondary nozzle with the position of the primary nozzle. In accordance with the analysis, the pressure in the throat is virtually

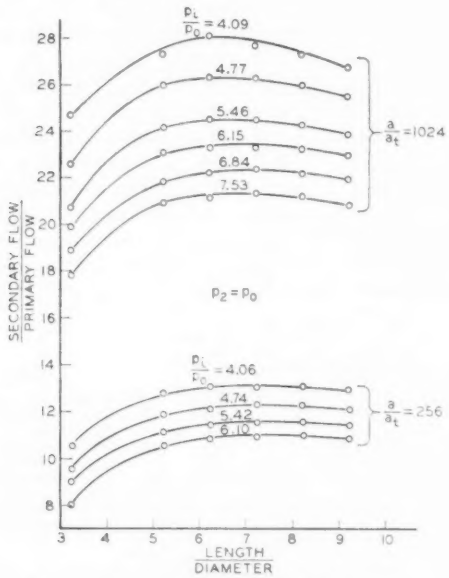

FIG. 7 EFFECT OF LENGTH OF MIXING TUBE
(Primary nozzle exit at entrance to secondary nozzle.)

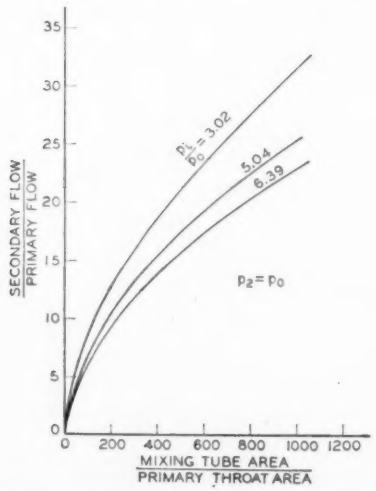

FIG. 8 EXPERIMENTAL CURVES SHOWING EFFECT OF AREA RATIO AND RATIO OF SUPPLY PRESSURES FOR BEST LENGTH OF MIXING TUBE AND BEST POSITION OF NOZZLE

at a minimum when the primary nozzle discharges into the throat of the secondary nozzle. In this instance, the flow ratio is also within a fraction of 1 per cent of its maximum value. The small effect at this area ratio (256) of thickness of the walls of the primary nozzle is indicated by the agreement between the results for two nozzles having the same throat diameter but different external dimensions.

The effect of the length of the mixing tube on the flow ratio for zero pressure rise across the mixing tube is shown in Fig. 7. The primary nozzle is placed at the best position, as indicated by the data of Fig. 6. In this instance, there is some evidence that the best length increases with increase in the ratio of the initial pressures p_i/p_0 and with increase in the relative size of the nozzle. Nevertheless, a value of L/D of 7 will give nearly the best performance throughout the range of conditions investigated.

The effect of area ratio on the flow ratio is shown by the experimental curves of Fig. 8. The data corresponding to these curves are compared with the results of analysis in Fig. 9.

COMPARISON OF EXPERIMENTAL VALUES WITH ANALYTICAL VALUES

In Fig. 9 are shown experimental and analytical values of the flow ratio for four different area ratios. The pressure rise across

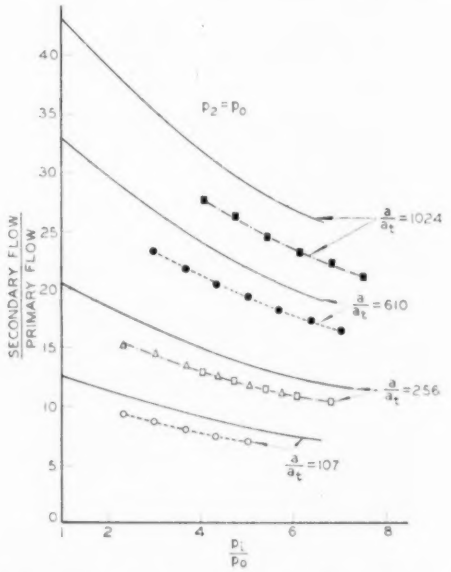

FIG. 9 COMPARISON OF MEASURED AND CALCULATED VALUES OF FLOW RATIO
(Solid lines indicate calculated values; broken lines, measured values.)

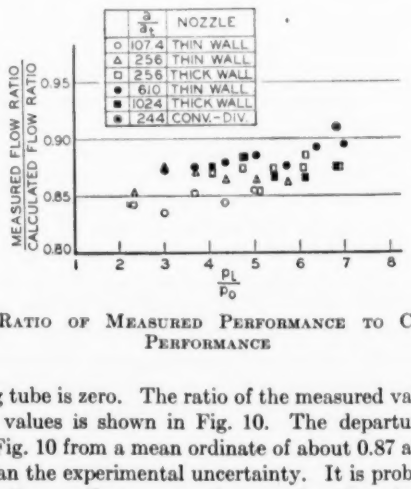

FIG. 10 RATIO OF MEASURED PERFORMANCE TO CALCULATED PERFORMANCE

the mixing tube is zero. The ratio of the measured values to the analytical values is shown in Fig. 10. The departures of the points of Fig. 10 from a mean ordinate of about 0.87 are scarcely greater than the experimental uncertainty. It is probable, however, that the smallest area ratio, namely, 107, gives slightly lower values of the ordinate than the others. It is also probable that the high value of the ordinate for the converging-diverging nozzle is significant.

Measured values of the pressure in the throat of the secondary nozzle are compared with analytical values in Fig. 11. The pres-

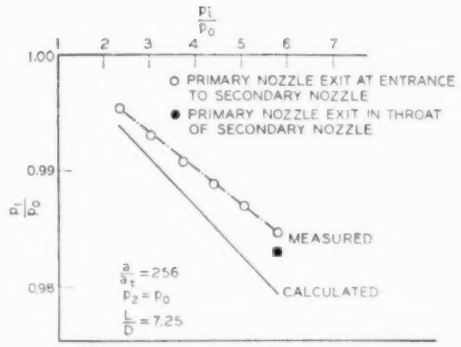

FIG. 11 COMPARISON OF MEASURED AND CALCULATED VALUES OF PRESSURE IN THROAT OF MIXING TUBE

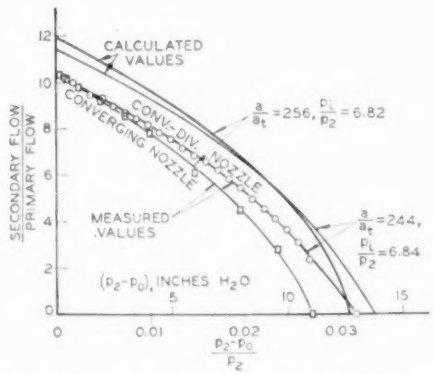

FIG. 12 COMPARISON OF MEASURED AND CALCULATED PERFORMANCE WITH VARIATION IN PRESSURE RISE ACROSS SECONDARY STREAM

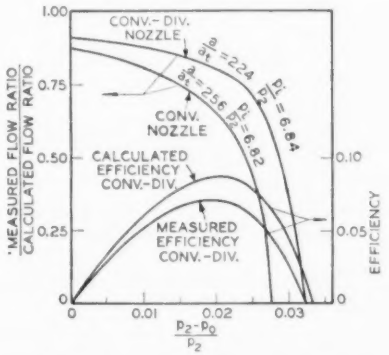

FIG. 13 EFFECT OF VARIATION IN PRESSURE RISE ACROSS SECONDARY STREAM

sure rise across the secondary stream is zero. The measured curve could be obtained from the analytical one by multiplying values of 1 minus the ordinate by 0.75. If the primary-nozzle exit is in the throat of the secondary nozzle, the multiplier is 0.83.

When the ejector is used as a pump to raise the pressure of the secondary stream through a finite range, the flow ratio decreases with increasing pressure rise ($p_2 - p_0$) for the secondary stream. Fig. 12 shows the measured and calculated performance for an ejector with a converging nozzle and with a converging-diverging nozzle having a divergence ratio appropriate to the conditions of the test. The performance with the converging-diverging nozzle is only slightly better when the pressure rise is small, but it is much better when the pressure rise is large. For the pressure rise at which the converging nozzle gives zero secondary flow, the converging-diverging nozzle gives a flow ratio of 2.5. The characteristics of the experimental and analytical curves are similar.

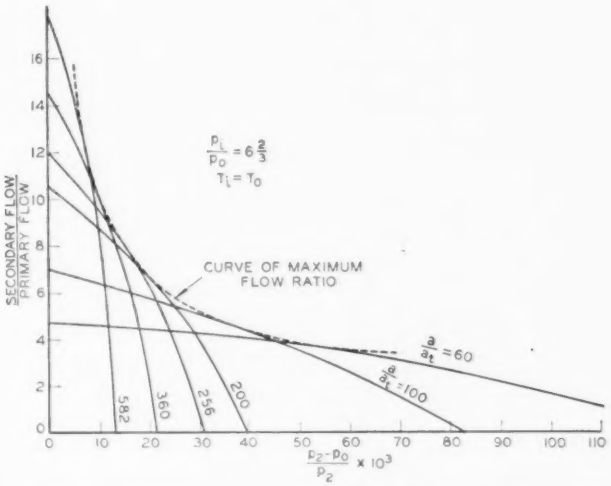

FIG. 14 CALCULATED PERFORMANCE OF THE SIMPLE EJECTOR

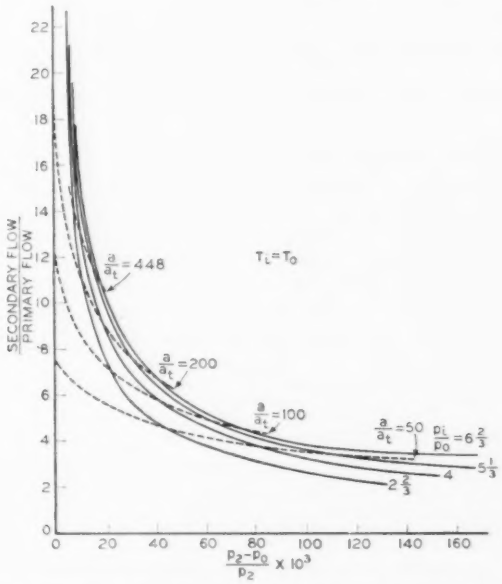

FIG. 15 CURVES OF MAXIMUM FLOW RATIO FOR SIMPLE EJECTOR AT DIFFERENT PRESSURE RATIOS

The ratio of the measured flow ratio to the calculated flow ratio for the tests of Fig. 12 is shown in Fig. 13. Since the analytical value for the pressure rise at zero secondary flow is not realized with either type of nozzle, the values of the ordinate of Fig. 13 must go to zero when the secondary flow goes to zero. Nevertheless, the ordinate holds up remarkably well over most of the range. For the converging nozzle it falls from 0.87 to 0.8 as the pressure rise increases to one third its maximum value; for the converging-diverging nozzle it falls from 0.89 to 0.8 only after the pressure rise increases to two thirds its maximum value.

This extraordinarily good agreement between experimental and analytical results justifies the computation of curves such as those of Figs. 14 and 15, to serve as guides in the design of ejectors. Fig. 14 shows that, for fixed values of the inlet and outlet pressures, there is a best area ratio. The calculated performance, corresponding to these best area ratios, is shown in Fig. 15.

Calculated and measured values of the efficiency of an ejector

with a converging-diverging primary nozzle are shown in Fig. 13. The efficiency, which credits the ejector with none of the leaving kinetic energy, is defined as the ratio of the isentropic increase in the enthalpy of the secondary stream between inlet and p_2 to the isentropic decrease in the enthalpy of the primary stream between inlet and p_2.

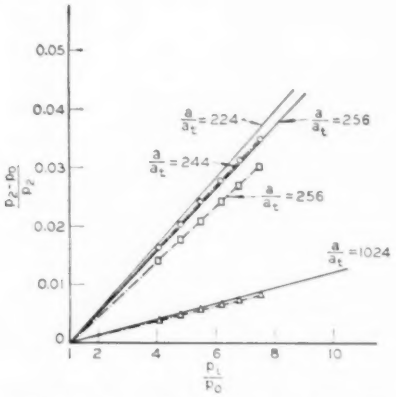

FIG. 16 PRESSURE RISE ACROSS MIXING TUBE FOR ZERO SECONDARY FLOW

(Solid lines indicate calculated values; broken lines indicate measured values.)

When the secondary flow is zero the analysis is that for a sudden enlargement of a passage. The corresponding values of the pressure rise across the mixing tube for various area ratios are compared in Fig. 16 with the measured values. Again, experimental and analytical curves are alike in characteristics; in fact the experimental curves for converging nozzles can be obtained quite accurately by multiplying the ordinates of the analytical curves by 0.9, and those for converging-diverging nozzles by multiplying by 0.95.

SUMMARY

1 In a simple ejector consisting of a primary nozzle and a cylindrical mixing tube with rounded entrance, constant-area mixing is better than constant-pressure mixing except for area ratios less than 10 (where some combination of the two is better than either one).

2 The performance of the simple ejector can be calculated from the conditions imposed by conservation of matter, conservation of energy, and the laws of motion.

3 Experiments on the simple ejector show that (*a*) the best position of the exit of the primary nozzle is only a short distance upstream from the throat of the secondary nozzle, and that a position in the throat of the secondary nozzle is practically as good; (*b*) the best length of the mixing tube is slightly greater than 7 diam; (*c*) the ratio of secondary flow to primary flow increases rapidly with the ratio of mixing-tube area to nozzle-throat area, and decreases with increase in the ratio of primary-supply pressure to secondary-supply pressure.

4 For zero pressure rise across the secondary stream (*a*) the experimental flow ratio is approximately 87 per cent of the calculated flow ratio for a converging primary nozzle, and approximately 91 per cent for a converging-diverging nozzle; (*b*) the pressure in the throat of the secondary nozzle is less than the secondary-supply pressure by 83 per cent of the calculated amount, when the exit of the primary nozzle is in the throat of the secondary nozzle.

5 The pressure rise in the secondary passage for zero secondary flow is 90 per cent of the calculated value for a converging nozzle, and 95 per cent for a converging-diverging nozzle.

Appendix

Consider the ejector shown in Fig. 17. Assume the following conditions: (*a*) Primary and secondary fluids are identical and incompressible; (*b*) the process (i-x) in the primary stream between the primary supply chamber and the exit of the primary nozzle is reversible; (*c*) the corresponding process (0-x) in the secondary stream is also reversible; (*d*) between sections x and 1 the two streams mix at constant pressure without wall friction, but mixing is, in general, incomplete at section 1; (*e*) between sections 1 and 2, mixing proceeds at constant cross-sectional area without wall friction; (*f*) the velocity of the fluid is uniform across section 2.

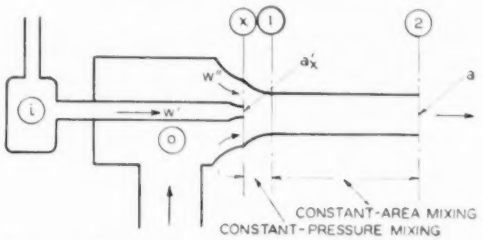

FIG. 17 EJECTOR DIAGRAM USED FOR ANALYSIS

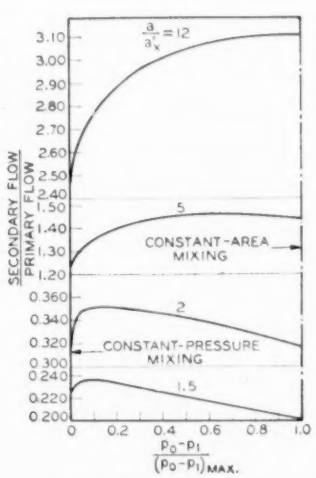

FIG. 18 PERFORMANCE OF EJECTOR FOR VARIOUS DEGREES OF MIXING AT CONSTANT PRESSURE

Using superscripts $'$ and $''$ for primary and secondary streams, respectively, and subscripts 0, x, and 2 to denote corresponding sections in Fig. 2, we may write the momentum equation between sections x and 2 in the form

$$\frac{w}{g} V_2 + p_2 a = \frac{w'}{g} V_x' + \frac{w''}{g} V_x'' + p_x a \quad \ldots\ldots [9]$$

where the symbols have the same connotation as in Equations [1] to [6]. Using the relations

$$V = \frac{wv}{a}, \quad V_x' = \frac{w'v}{a'_x}, \quad V_x'' = \frac{w''v}{a_x''}$$

we get Equation [9] in the form

$$\frac{w^2 v}{ga} + p_2 a = \frac{w'^2 v}{g a_x'} + \frac{w''^2 v}{g a_x''} + p_x a \quad \ldots\ldots [10]$$

Let $\omega = \frac{w''}{w'}$, $\alpha = \frac{a}{a_x'}$, and $\alpha'' = \frac{a}{a_x''}$. Noting that $w = (1 + \omega)w'$

we get from Equation [10]

$$1 + 2\omega + \omega^2 - \alpha - \alpha''\omega^2 + (p_2 - p_x)\left(\frac{a}{w'}\right)^2 \frac{g}{v} = 0 \ldots [11]$$

Let us restrict the problem to zero pressure rise across the secondary stream, that is, to $p_2 = p_0$. Then $p_2 - p_x = p_0 - p_x$, and, by assumption (*c*)

$$(p_2 - p_x) = \frac{V_x''^2}{2gv} = \left[\frac{\omega w' \alpha''}{\alpha}\right]^2 \frac{v}{2g}$$

Substituting this into Equation [11], we get

$$\left(1 - \alpha'' + \frac{\alpha''^2}{2}\right)\omega^2 + 2\omega + 1 - \alpha = 0 \ldots\ldots [12]$$

If we fix values for the area ratios α and α'', then Equation [12] is a quadratic in ω which may be readily solved. When sections x and 0 coincide then α'' is zero. Moreover, since $p_x - p_0 = 0$, it follows that, $p_2 - p_1 = 0$, and, therefore, no mixing occurs at constant area. Thus, sections 1 and 2 must coincide. This is the case of complete mixing at constant pressure for which Equation [12] becomes

$$\omega^2 + 2\omega + 1 - \alpha = 0 \ldots\ldots\ldots\ldots [13]$$

When sections x and 1 coincide, then $a = a_x' + a_x''$ and $\alpha'' = \frac{\alpha}{\alpha - 1}$. This is the case of complete mixing at constant area, for which Equation [12] becomes

$$\left[1 - \frac{\alpha}{\alpha - 1} + \frac{1}{2}\left(\frac{\alpha}{\alpha - 1}\right)^2\right]\omega^2 + 2\omega + 1 - \alpha = 0 \ldots [14]$$

Fig. 2 shows ω as a function of α corresponding to Equations [13] and [14]. In the same figure is shown ω as computed from Equation [12] as a function of the pressure rise $(p_2 - p_1)$ or $(p_0 - p_1)$ divided by the pressure rise $(p_0 - p_1)_{max}$ corresponding to complete mixing. It is easily seen from the foregoing analysis that

$$\left[\frac{p_0 - p_1}{(p_0 - p_1)_{max}}\right] = \left[\frac{\alpha''(\alpha - 1)}{\alpha}\right]^2$$

Although Fig. 2 indicates that the best performance is obtained for a given area ratio α with complete mixing at constant area, there is an exception to this rule, as shown by Fig. 18. For area ratios less than about 5, the best performance is obtained with more or less mixing at constant pressure. It appears that, for very small area ratios, it is desirable to discharge the primary nozzle outside the throat of the secondary nozzle, even under the idealized conditions of the analysis.

Graphical Solution of Fluid-Friction Problems

By E. S. DENNISON,[1] GROTON, CONN.

It is customary to present fluid-friction data in the form of a diagram to log scale in which friction coefficient appears as a function of Reynolds number. Such data are widely applicable to physical circumstances other than those which pertained to the original experiments. The present paper describes a graphical procedure for utilizing data of this character, where analytical methods are not practicable, and resort is made to trial-and-error methods. Similar methods to that described may be found useful in other fields than that of fluid friction, provided the experimental data are capable of being represented in nondimensional form.

THE data in any general case of fluid friction are commonly presented in the form of a diagram in which friction coefficient appears as a function of Reynolds number, both to log scales. This nondimensional method of plotting serves to identify all states of flow for which the dynamical conditions are similar. As a result, the data can be applied to physical circumstances which may be widely different from those of the original experiments.

In making use of friction data in this form, it is frequently required to find a solution in terms of some variable, for example velocity, which appears both in the friction-coefficient group ($= \psi$) and in the Reynolds-number group ($= R$). In the laminar region there is an explicit relation between ψ and R, and the analytical solution is simple. At higher values of R, the ψ-R relation is empirical and irregular. No analytical solution is practicable, and it is usually necessary to resort to a trial-and-error method. This is a time-consuming process.

The purpose of this paper is to describe a graphical procedure which can be used to solve the ψ-R equation directly in terms of the required variable. The method is simple in application, and introduces no error beyond what is common to graphical constructions. It will be explained by discussing certain common cases having to do, respectively, with terminal speed of a falling sphere and flow in a pipe. Similar methods may prove useful in other fields than that of fluid friction, provided that the experimental data are capable of being represented in nondimensional form.

Terminal Speed of a Falling Sphere

Resistance to motion of a sphere in a fluid medium is given by

$$r = \psi\rho \frac{v^2}{2} \cdot \frac{\pi}{4} d^2 \quad \ldots\ldots [1]$$

in which r = resisting force
ψ = coefficient of resistance, a number
ρ = density of fluid medium
v = velocity of motion
d = diameter of sphere

At terminal speed, resistance r equals the net gravitational force acting upon the sphere

$$r = \frac{\pi}{6} d^3(\sigma - \rho)g \quad \ldots\ldots [2]$$

in which σ = density of sphere
g = acceleration of gravity

From Equation [1]

$$\psi = \frac{8r}{\pi\rho v^2 d^2} \quad \ldots\ldots [1a]$$

Combining with Equation [2]

$$\psi = \frac{4}{3} g \left(\frac{\sigma - \rho}{\rho}\right) \frac{d}{v^2} \quad \ldots\ldots [3]$$

It is known that the coefficient ψ is a function of the Reynolds number, defined as

$$R = \frac{dv\rho}{\mu} \quad \ldots\ldots [4]$$

in which μ is the viscosity of the fluid. Stokes's law is valid in the laminar region and there $\psi = 24/R$, but this expression ceases to be accurate above $R = 0.5$. Fig. 1 represents $\log \psi$ as a function of $\log R$ over the extensive range for which data are available (1, 2).[2] Except in the narrow laminar region, the function cannot be expressed algebraically.

Technical application of the theory of terminal speeds, with special reference to spherical particles, leads to the following two cases (1):

I Given particle diameter and other necessary data, to compute terminal velocity.

II Given terminal velocity and other necessary data, to compute particle diameter.

In each case the variable sought appears in both ψ and R. What is required is the solution of two simultaneous equations. Graphical methods for effecting this result will be described in the following sections.

I *Computation of Terminal Velocity.* The curve in Fig. 1 represents the equation

$$\log \psi = f(\log R) \quad \ldots\ldots [5]$$

or

$$\log \left[\frac{4}{3} g \left(\frac{\sigma - \rho}{\rho}\right) \frac{d}{v^2}\right] = f\left[\log \left(\frac{dv\rho}{\mu}\right)\right] \quad \ldots\ldots [5a]$$

Let

$$x_v = \log \left(\frac{d\rho}{\mu}\right) \quad \ldots\ldots [6]$$

$$= \log R - \log v \quad \ldots\ldots [6a]$$

and

$$y_v = \log \left[\frac{4}{3} g \left(\frac{\sigma - \rho}{\rho}\right) d\right] \quad \ldots\ldots [7]$$

$$= \log \psi + 2 \log v \quad \ldots\ldots [7a]$$

Then Equation [5] may be written

$$(y_v - 2 \log v) = f(x_v + \log v) \quad \ldots\ldots [8]$$

---

[2] Numbers in parentheses refer to the Bibliography at the end of the paper.

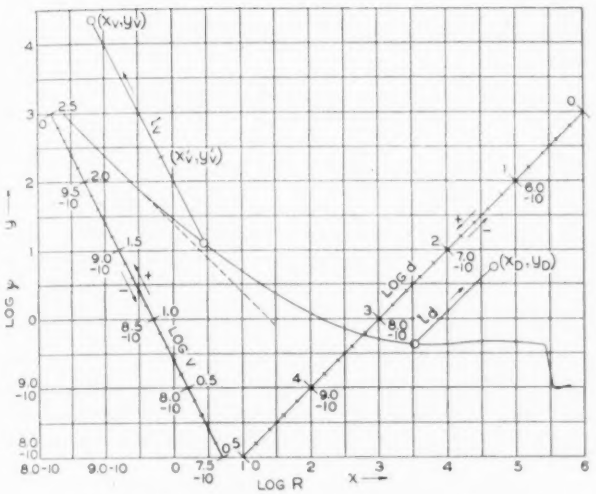

FIG. 1 TERMINAL SPEED OF A SPHERICAL PARTICLE

As a special case, when $v = 1$ (using any homogeneous system of units), $x_v = \log R$ and $y_v = \log \psi$. Then Equation [8] becomes numerically identical with Equation [5], and is represented by the curve in Fig. 1.

In general, a point (x_v, y_v) is displaced from the corresponding point (R, ψ) on the curve by the amounts $\Delta x = -\log v$ and $\Delta y = +2 \log v$. Therefore, all points corresponding to a state of flow (R, ψ) lie in a line passing through that point and having the slope -2. Furthermore, the distance l_v measured diagonally from (R, ψ) to (x_v, y_v) is $\sqrt{2^2 + 1} \log v = \sqrt{5} \log v$.

The data for a problem of type I permit x_v and y_v to be computed. An axis for $\log v$, having the proper slope and suitably graduated, has been added to Fig. 1. It is only necessary to locate (x_v, y_v) on the diagram and pass a line through it parallel to the $\log v$ axis. This line will intersect the curve at some point (R, ψ). The Reynolds number and resistance coefficient for the case in question are thus fixed at once. Velocity is found by laying off length l_v on the $\log v$ scale. If (x_v, y_v) lies above the curve, $v > 1$ (i.e., $\log v$ is positive); if below, $v < 1$.

In the foregoing, it will be noticed that a second diagram, the co-ordinates of which are dimensional in $\log v$, has in effect been superposed on the original nondimensional diagram. The geometrical construction is made in the dimensional plane. Displacements are measured from the data curve where $\log v = 0$.

The construction for a possible pair of values (x_v, y_v) is included in the diagram by way of illustration. Any consistent set of units may be used, and with a change in the unit of velocity, point (x_v, y_v) will merely shift up or down the same sloping line. Should (x_v, y_v) be found to lie outside the limits of the diagram, this can be adjusted by an arbitrary change of units. For example, plot $x'_v = x_v + 1$ and $y'_v = y_v - 2$, as in the figure. Velocity is then measured in a new unit 10 times as large as the original.

II *Computation of Diameter.* The reasoning is similar to that just outlined. In this case

$$x_d = \log\left(\frac{\rho v}{\mu}\right) \quad [9]$$

$$= \log R - \log d \quad [9a]$$

and

$$y_d = \log\left[\frac{4}{3}\frac{g}{v^2}\left(\frac{\sigma - \rho}{\rho}\right)\right] \quad [10]$$

$$= \log \psi - \log d \quad [10a]$$

Equation [5] becomes

$$(y_d + \log d) = f(x_d + \log d) \quad [11]$$

All points (x_d, y_d), for which R and ψ are constant, lie in a line having the slope $+1$. The distance $l_d = \sqrt{2} \log d$. Fig. 1 includes an axis for $\log d$, suitably graduated. In the region above and to the right of the curve $d < 1$; below and to the left $d > 1$. The procedure in case II parallels that given for case I. The construction is illustrated by an example.

FLOW IN A CIRCULAR PIPE

One form of the equation for frictional loss in a long straight circular pipe is

$$\Delta p = \lambda \rho \frac{u^2}{2} \frac{L}{D} \quad [12]$$

in which
- Δp = pressure loss due to fluid friction
- λ = pipe-friction coefficient, a number
- ρ = density of fluid
- u = mean velocity of flow
- L = pipe length
- D = pipe diameter

It is known that the coefficient λ is a function of the Reynolds number, $R = Du\rho/\mu$. In the laminar region $\lambda = 64/R$. At and above the critical range (R = 1200–2400) no simple algebraic relation exists, although for the turbulent region approximate expressions such as $\lambda = \text{const} \cdot R^n$ have been used. Frictional resistance varies with the relative roughness of the pipe wall, hence a number of curves representing $\lambda = f(R)$ are required. Fig. 2 includes a series of such curves as given by Pigott (3), although several have been omitted to avoid crowding. The reference should be consulted regarding the type of conduit to which each numbered curve applies. Of the two extremes, 18 represents "entirely rough" pipe ($\lambda = 0.054$) and 19, "lowest values for drawn brass tube." Many other sources of friction data are available (2, 4).

Two pipe-flow problems in which the graphical method can be used to advantage will be discussed. Both of these represent cases frequently encountered in practice.

III Given properties of the fluid, length and diameter of pipe, and pressure drop, to compute flow velocity.

IV Given properties of the fluid, volume rate of flow, length of pipe, and permissible pressure drop, to compute the requisite diameter of pipe. This is typical of the case where a pipe size is to be selected in order to meet a design specification.

III *Computation of Flow Velocity.* From Equation [12]

$$\lambda = \frac{2D \cdot \Delta p}{\rho u^2 L} \quad [12a]$$

Since

$$\log \lambda = f(\log R) \quad [13]$$

$$\log\left(\frac{2D \cdot \Delta p}{\rho u^2 L}\right) = f\left[\log\left(\frac{Du\rho}{\mu}\right)\right] \quad [13a]$$

Let

$$x_u = \log \frac{D\rho}{\mu} \quad [14]$$

$$= \log R - \log u \quad [14a]$$

and

$$y_u = \log\left(\frac{2D \cdot \Delta p}{\rho L}\right) \quad [15]$$

$$= \log \lambda + 2 \log u \quad [15a]$$

Equation [13] becomes

$$(y_u - 2 \log u) = f(x_u + \log u) \quad [16]$$

The data of the problem permit x_u and y_u to be computed.

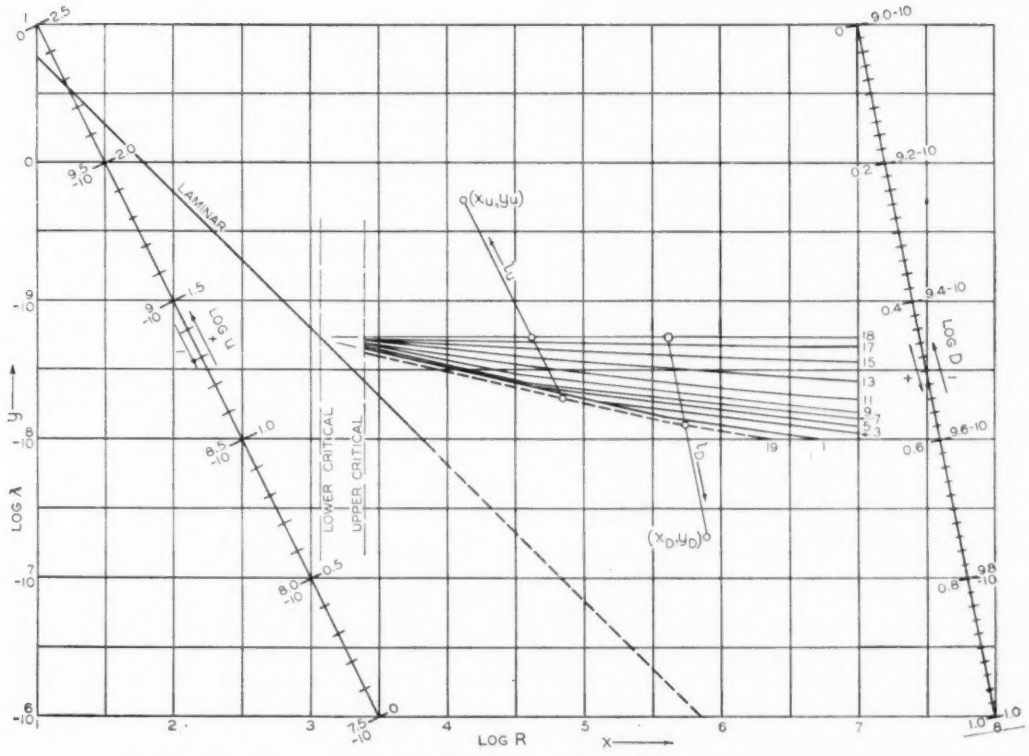

FIG. 2 FLOW IN A CIRCULAR PIPE

The point being plotted in the diagram, Fig. 2, will be displaced from the point (R, λ), representing the state of flow, by the amounts $\Delta x = -\log u$ and $\Delta y = +2 \log u$. As in case I, all such points lie in a line having the slope —2. The diagonal length l_u from (R, λ) to (x_u, y_u) is equal to $\sqrt{5} \log u$.

A graduated axis for log u, of proper slope, is given in Fig. 2. In the region above the curve, $u > 1$; below it $u < 1$. The construction is illustrated.

A useful feature of the graphical solution, in this case and in case IV, is that a single construction gives the result for each grade of pipe which the designer may wish to consider.

IV *Computation of Pipe Diameter.* Let Q = volume rate of discharge. Then in a circular pipe

$$u = 4Q/\pi D^2 \quad [17]$$

Substituting in Equation [12*a*]

$$\lambda = \frac{\pi^2 D^5 \cdot \Delta p}{8\rho L Q^2} \quad [18]$$

Also
$$R = \frac{Du\rho}{\mu} = \frac{4Q\rho}{\pi D\mu} \quad [19]$$

Then
$$\log\left(\frac{\pi^2 D^5 \cdot \Delta p}{8\rho L Q^2}\right) = f\left[\log\left(\frac{4Q\rho}{\pi D\mu}\right)\right] \quad [13b]$$

Let
$$x_D = \log\left(\frac{4Q\rho}{\pi\mu}\right) \quad [20]$$

$$= \log R + \log D \quad [21]$$

Also
$$y_D = \log\left(\frac{\pi^2 \cdot \Delta p}{8\rho L Q^2}\right) \quad [22]$$

$$= \log \lambda - 5 \log D \quad [23]$$

Equation [13] then becomes

$$(y_D + 5 \log D) = f(x_D - \log D) \quad [24]$$

Computing x_D and y_D from the data, the plotted point will be displaced by $\Delta x = \log D$ and $\Delta y = -5 \log D$ from the corresponding flow point (R, λ). Such points lie in a line whose slope is —5. The diagonal distance l_D is $\sqrt{5^2 + 1} \log D = \sqrt{26} \log D$. A graduated axis of proper slope has been added to the diagram and the construction is illustrated. Below the curve, $D > 1$; above it $D < 1$.

The solution yields directly the diameter of pipe required, together with the Reynolds number and friction coefficient at which it will operate. Results are found simultaneously for each grade of pipe represented in the diagram.

CONCLUSION

The graphical methods described in the paper are based upon the use of a simple mathematical device. In the problems discussed, the effect is to substitute a direct and rapid solution in place of a trial-and-error solution. It is possible that similar methods may be found useful in other instances, where experimental data have been assembled in nondimensional form.

Correlation of Residual Stresses in the Fatigue Strength of Axles

By O. J. HORGER[1] and H. R. NEIFERT,[2] CANTON, OHIO

The object of this paper is to present a correlation between residual stresses, obtained by heat-treatment, with fatigue values, determined from an investigation of full-size railroad axles. The axles tested were of both solid and tubular design and represent members which could be used under a car in actual service. It was found from these tests that high axle fatigue strength is associated with high surface residual compressive stresses, and lowest axle strength values with surface residual tensile stresses.

Introduction

THERE is some question on the part of engineers as to the proper manner of evaluating residual stresses in their influence upon the fatigue strength of members subjected to a nonuniform distribution of stresses, such as are produced by bending or torsional loading. It is often felt that residual stresses obtained by heat-treatment are deleterious or have little effect upon fatigue strength; on the other hand, it is occasionally considered that certain kinds of residual stresses are favorable and other kinds unfavorable. This divergence of opinion may be explained by the small amount of experimental evidence available regarding fatigue strength, where the influence of residual stresses has been isolated from other factors. Often, changes in microstructure accompany any variation made in residual stresses, so that many fatigue investigations show the influence of both residual stresses and microstructure.

The comprehensive review of this subject by Barrett (1)[3] mentions, among other factors besides residual stresses involved in the results of reported investigations, (*a*) homogenization during the stress-relieving anneal; (*b*) possible "cushioning" effect of retained austenite; (*c*) microscopic stresses. Investigations have been reported by Gough (2), Gillett and Mack (3), French (4), Sachs (5, 6), and Becker and Phillips (7), showing that internal stresses may be controlled so as to be helpful or harmful. Unfortunately, these references give little correlating data between the magnitude of the internal stresses and the fatigue values; seldom were residual stresses isolated from other factors. Residual surface compressive stresses, obtained by cold-working, are known to increase greatly the fatigue strength of specimens over that for those not cold-worked. Here again, there is a difference of opinion as to whether residual stresses or the accompanying changes in the material are responsible for this increase in fatigue strength. The investigation, reported in this paper, however, is concerned only with residual stresses due to some form of heat-treatment.

Correlation of residual stresses with reversed-bending endurance values was obtained by Bühler and Buchholtz (8) on plain specimens about 0.71 and 1.07 in. diam. Their results represent the best quantitative analysis available and, for this reason, a diagrammatic summary of their findings is given in Figs. 1 and 2. Residual stresses were determined by Sachs's boring-out method (9). Their data indicate that (*a*) the endurance limit can be increased 15 to 20 per cent by high compressive stresses at the boundary, produced by quenching from a temperature below the A_1 point, without change in tensile properties; (*b*) the endurance limit can be decreased by about 15 per cent by high tensile stresses at the boundary (less than about 28,000 psi residual tensile stress did not have a damaging effect on the fatigue strength); (*c*) during the fatigue test, the magnitude of residual stresses at the surface leveled off (in one case the initial residual tensile stresses at the surface were reversed into residual compressive stresses by the alternating stress without damaging the fatigue strength); (*d*) measurable residual stresses at the boundary can be produced by alternating loading below or even at the endurance limit (a partial explanation for the well-known favorable effect of understressing).

In order to obtain residual stresses, it is necessary that plastic deformations of unlike magnitude occur in different zones of the member. Residual stresses may arise in cooling from (*a*) unequal contraction through pure thermal stresses, or (*b*) change in volume in passing through the transformation point. The hypothesis for the effectiveness of surface residual compressive stresses in these tests is that the zero-to-maximum fatigue strength of the steel is greater with compressive loading than with tensile loading. The presence of internal stresses is also manifested by the Bauschinger effect (10) and modification of damping capacity but these effects are not discussed here.

No correlation similar to that mentioned is known to exist for the case of members having stress concentration. The fatigue tests and associated determinations of residual stresses reported in this paper attempt partially to fill this gap. The tests reported on the solid axles and type A tubular axles were made under the auspices of the Mechanical Division of the Association of American Railroads, and through the direction of an axle committee under the chairmanship of W. I. Cantley, mechanical engineer (11). Type B tubular axles were investigated as a separate project by the authors' company in order to contribute additional data pertaining to the fatigue strength of axles.

Axle and Wheel Assemblies Tested

Three different designs of axles were investigated as indicated in Fig. 3. Two of these designs were tubular axles, designated as types A and B, and the third was a solid axle of conventional design. An equivalent wheel was pressed on each test axle, as shown in Fig. 3 (*c*), in accordance with the usual mounting practice of railroad shops.

Processing details as to rolling, forging, heat-treatment, and machining of the solid and tubular axles were previously published (12).

Material. Axles from five different materials were tested, in

which the analysis conformed essentially to S.A.E. 1040 and 1045 steels as shown in Table 1. The physical properties given in Table 2 represent minimum and maximum values obtained from a large number of specimens machined from the test axles. The disks, representing wheels pressed on these axles, were in accordance with A.A.R. Specification M-107-36 for "Multiple-Wear Wrought Steel Wheels." The scleroscopic hardness of these wheels was 35 to 37, as measured on the end of the hub face midway between the bore and outside diameter of the hub.

FATIGUE-TEST METHOD

These axles were tested on large double-end rotating cantilever-beam fatigue machines (12). The axle is supported in the test machine by bolting the rim of the wheel to a rotating head of the fatigue machine which operates at 800 to 1500 rpm. A constant spring load is applied on the opposite axle journal. This

method of loading, shown in Fig. 3 (*c*), applies a bending moment on the axle of the same shape as that used by the designer when calculating a combination of vertical and lateral forces (Reuleaux method) to determine axle size.

The stress expressed here refers to the nominally calculated axle-bending stress at the end of the wheel fit. This is shown diagrammatically in Fig. 3 (*c*), where the bending moment is equal to *PL* and this product is divided by the section modulus of the axle to obtain the bending stress. For convenience of comparisons made later, the allowable bending stress for the tubular axles is given as the equivalent stress on a solid axle of the same wheel-seat diameter. This procedure is logical if we assume the axle forces produced in service to be the same whether a hollow or solid axle is used. In this manner the load-carrying capacity of the solid and tubular axles of the same wheel-seat diameter may be compared directly from the endurance-limit values, without considering how the section modulus is altered by the presence of the hole.

Endurance-limit values are based on a test of at least 84,300,000 axle revolutions which corresponds to an equivalent of 150,000 miles on 36-in-diam wheels.

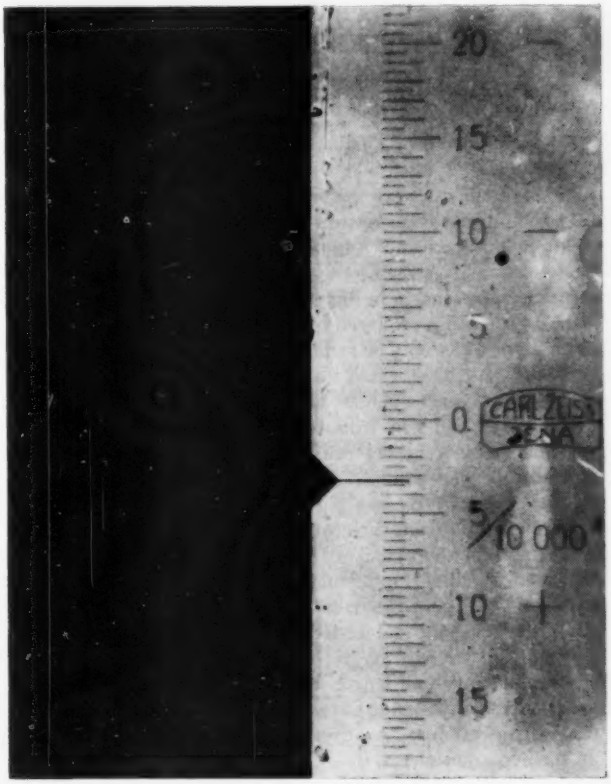

FIG. 5 REPRODUCTION OF SCALE IN ZEISS OPTIMETER TO SHOW ACCURACY OF MEASUREMENTS

DETERMINING RESIDUAL STRESSES

It was desired to determine the residual stresses in the axle wheel seat so that this portion (Fig. 3c) was machined from one full-size axle of each of the various types which had not been subjected to a fatigue test. These sections were ground on the outside diameter and ends with an extremely smooth finish to permit accurate measurements. Dimensions of these cylinders ranged from 7 to $7^{9}/_{16}$ in. diam by $7^{9}/_{16}$ in. length, and the hollow members had a $3^{1}/_{2}$-in-diam hole in type A, and $4^{7}/_{16}$-in. hole in type B axles.

Each cylinder was successively bored out on an engine lathe in accordance with Sachs's method (9, 13, 14) and the changes in cylinder length and outside diameter were determined after each removal of 5 to 10 per cent of the cross-section area. The solid cylinders were first bored with a $1^{3}/_{4}$-in. hole. In order to minimize the effects of heating and machining stresses, a very small amount of metal was removed in each boring, using a coolant. A series of cuts was required for each 5 to 10 per cent removal of cross-section area. An effective means of preventing deep boring cuts was employed by clamping the cylinder endwise against the face plate on the lathe and using no radial clamping force on

the cylinder. Too deep a cut would loosen or move the cylinder on the face plate.

All measurements were made on the cylinders after they had reached equilibrium temperature conditions in a gage room which was air-conditioned and the temperature and humidity maintained constant. A Zeiss optimeter was employed to make all measurements as shown in Fig. 4. The accuracy of measurement is indicated in the reproduced optimeter scale in Fig. 5, showing that direct readings may be made to 0.0001 in. and estimated with no difficulty to 0.000025 in.

Diameters of each cylinder were measured at three sections, i.e., the center, and 1 in. from either end. Maximum and minimum diameters were determined so that an average of six measurements was obtained between each series of boring-out operations. Length measurements were made every 90 deg and at each 90-deg position three measurements were made through the thickness of the cylinder. Twelve measurements were obtained in this manner by having one end of the cylinder rest on the base of the gage. The cylinder was then turned upside down so that the opposite end rested on the base of the gage, and other similar twelve length measurements were obtained. Then these twenty-four length measurements permitted drawing contour curves of the ends of the cylinder between each series of boring-out operations. An average length change was deduced from such contour curves.

This procedure of measuring, while tedious, was believed to be necessary because of the fact that the cylinder diameter and length were of about the same magnitude. In this manner any end effect[4] would be detected by distortion from a uniform cylinder to one which was larger or smaller in diameter at the ends than in the middle. Also, the ends of the cylinder would become concave or convex. It would have been desirable to have the cylinder length at least three times the diameter but the axle design did not permit this. The ratio used introduces some end effect and error in the residual stresses determined.

A comparison of the length and diameter changes as well as the calculated residual stresses for all cylinders is shown in Fig. 6. It will be noted that it was necessary to extrapolate the length and diameter changes to the surface of the specimens after the wall thickness was reduced to about $^3/_{16}$ in. This procedure is not desirable because some types of stress gradients near the surface could produce deformations deviating considerably from the extrapolated values. For this reason, future research is being directed toward turning off the outer layers and measuring changes in inside diameter and length. The same accuracy of measurements can be obtained as used in the boring-out method. Since the surface stresses are believed to be the most important on solid members, this latter method would not require the determination of the entire internal-stress distribution. Therefore, the number of layers to be machined away would be reduced as well

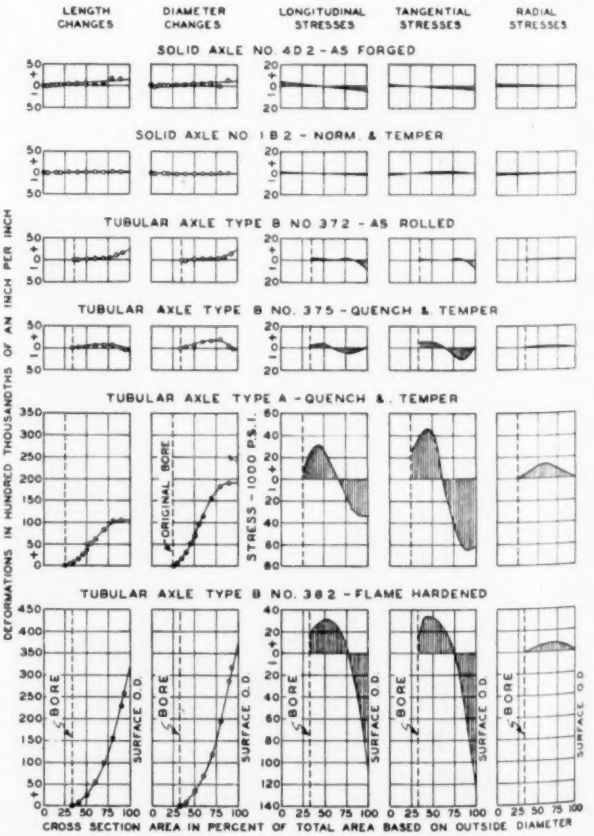

FIG. 6 COMPARISON OF RESIDUAL STRESSES AND DEFORMATIONS IN VARIOUS SOLID AND TUBULAR AXLES

[4] Treatment of end effect is discussed on page 355 of reference (14) for a solid cylinder, indicating that appreciable error in residual-stress determinations may be introduced by using a ratio of cylinder length to diameter of 1. Hollow cylinders having this ratio also introduce errors unless the wall thickness is less than about $^1/_{10}$ of the radius, as discussed on page 404 of reference (15).

Detailed measurements of the two cylinders, having the greatest internal stresses, showed about 10 per cent less increase in outside diameter at the center of the cylinder than obtained 1 in. from either end. This means that the internal stresses given here are too high. After completion of these tests, S. Timoshenko suggested that the influence of the portions of the axle protruding at each end of the wheel fit should be determined. Measuring the diameter and length of the wheel seat before and after machining it from the axle would give data on this question, but the opportunity to make this study has not yet presented itself.

as the number of measurements so as to lower the cost and time element in this work considerably.

Correlating Residual Stresses and Fatigue Strength

The relationship between the surface residual stresses, Fig. 6, and the fatigue strength, obtained for the various axles, is shown in Table 3 and diagrammatically illustrated in Fig. 7. The general observations from this comparison are (*a*) that, in the order of their maximum fatigue strength, axles also exhibit the maximum surface residual compressive stresses, and (*b*) axles having surface residual tensile stresses are also accompanied by low fatigue values.

It is not intended to infer from Fig. 7 that the internal stresses are entirely responsible for the differences in fatigue strength of the various axles. All axles except type A were of similar design. Real differences exist in the microstructure of the several axles. Additional research is under way to determine any influence of microstructure upon the fatigue strength. The preliminary indication from such additional research with members subjected to high stress concentration, such as an axle with a pressed-on wheel, is as follows:

For plain medium-carbon steel, the large grain size and accompanying structure found in an as-forged axle give appreciably greater fatigue strength than a finer grain structure, such as is obtained by normalizing and tempering. In this comparison, the residual stresses are small and are believed to have less influence

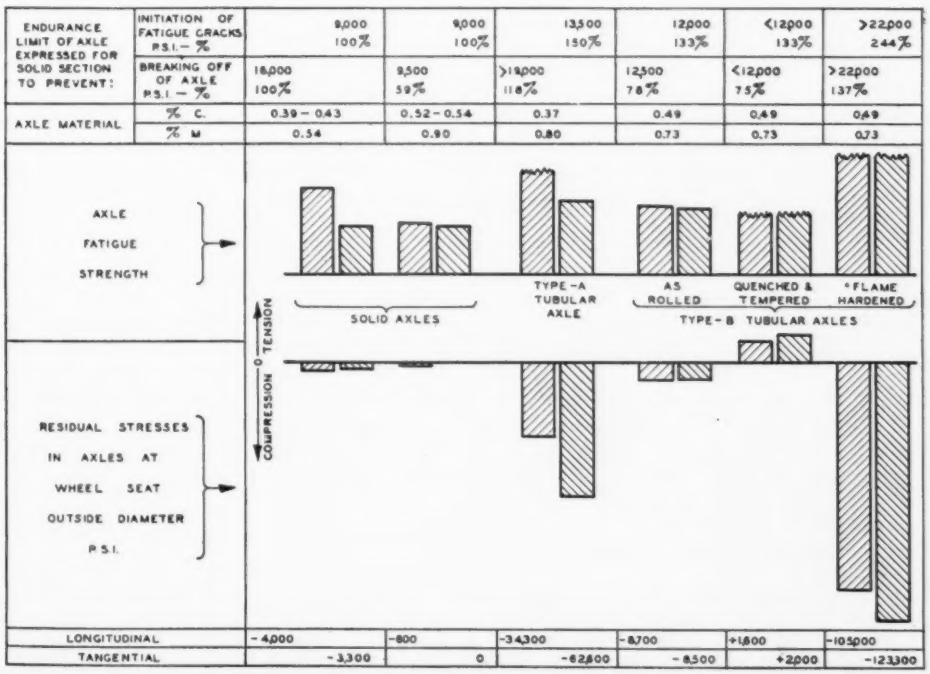

FIG. 7 DIAGRAMMATICAL CHART SHOWING RELATIONSHIP BETWEEN SURFACE RESIDUAL STRESSES AND FATIGUE STRENGTH

than the microstructure upon the fatigue strength. A possible explanation for this may be found from creep tests made at elevated temperature where a large grain structure exhibits superior creep properties than a finer grain structure. In these fatigue tests the local stresses are very high near the end of the wheel fit and some redistribution of stresses takes place. Another explanation may be that the type of structure accompanying large grain size is more resistant than the small grain size to the rubbing corrosion (fretting) occurring between the axle and wheel fit.

Plastic Flow as an Unstable Process

By L. H. DONNELL,[1] CHICAGO, ILL.

Instead of occurring simultaneously over regions which are apparently uniformly stressed, plastic flow frequently proceeds in a discontinuous manner, as in the formation of wedge-shaped plastic regions around the periphery of torsion specimens. It is contended in this paper that this phenomenon can be explained as an instability, brought about by stress concentrations which are caused, not by discontinuities in the shape of the specimen, but by the discontinuous behavior of the material around the yield point.

According to this explanation, yielding first occurs at some region of local weakness. The lagging of the stress in this yielded region causes a stress redistribution around the region, somewhat as if it were a hole, which retards stresses and therefore yielding in certain directions while accelerating them in other directions, thus leading to the spontaneous growth of characteristically shaped plastic regions.

Necking of Tensile Specimens

INSTABILITY is by definition a condition in which a small change in the state of a system brings into play forces or tendencies which increase the change, so that slight changes, which may occur accidentally, lead automatically to large changes.

A familiar example of unstable action in connection with plastic flow is the "necking," or localization of strain, which takes place during the latter part of a tensile test of a ductile material. This necking presumably starts with some slight accidental weakness of one section of the specimen relative to other sections, which is bound to be present because no specimen is absolutely uniform.

Due to its relative weakness, this section stretches slightly more under load than other sections. This slightly greater stretching is accompanied by slightly greater reduction of area, compared to other sections. This section is thereby still further weakened, which causes the stretching process to be yet further localized, and the section to be yet further reduced relative to other parts, etc., etc. The original accidental disturbance in the uniformity of the specimen thus starts a train of self-propagating actions, tending to localize the strains more and more.

There is also a "stabilizing" tendency present, in addition to the unstabilizing effects described. This stabilizing tendency is due to the phenomenon of strain hardening. This tends to make any section of the specimen which stretches more than other sections harder than the rest, and hence tends to inhibit further stretching at that section. These opposing tendencies are both present during most of a tensile test. It would be difficult to analyze them quantitatively, but it is evident that the stabilizing tendency is the dominant one up to the beginning of necking, at which time the unstabilizing tendency begins to dominate. The foregoing description is, of course, greatly oversimplified, although it probably includes the main factors affecting necking.

Plastic Flow in Bars Under Torsion

When a prismatical bar of ductile material such as mild steel is twisted until the yield point has been passed, studies of etched cross sections indicate that yielding has taken place in a highly discontinuous and yet remarkably regular manner.[2] In a circular bar, for example (the following discussion will be confined to circular bars for simplicity, although it applies equally well to other shapes), elastic theory indicates the stress to be a maximum and to be uniform in an annular region around the circumference, Fig. 1 (*a*). It would be natural to suppose therefore that, as the bar is twisted beyond the yield point, the regions of yielded material in the cross section would be more or less smooth annular regions which would be, successively, as indicated in Fig. 1 (*a*), (*b*), and (*c*).

Fig. 1

Fig. 2

Actually, the experiments show that yielding is confined, or at least is highly concentrated, in radial wedge-shaped regions in the cross section, which start at the periphery and gradually grow toward the center. As the yielding progresses, these regions grow in number as well as in size, but seem always to be distributed in a rather remarkably uniform manner about the circumference. They are quite slender but increase gradually in width as they grow in length, as indicated in Fig. 2 (*a*), (*b*), and (*c*), which shows typical successive stages of the process.

The author suggested an explanation for this phenomenon in a letter to Dr. Nádai in 1933, and it is this explanation which forms the bulk of this paper.[3] In brief the theory advanced is that the localization of the plastic flow is, like the necking in tensile tests, evidence of an unstable condition. In this case, the instability is caused by stress concentrations (it might be better to speak of strain concentrations in such a case as this, but the other term will be used because of its greater familiarity), which are caused, not by discontinuities in the shape of the

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until July 10, 1942, for publication at a later date. Discussion received after the closing date will be returned.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors and not those of the Society.

[2] "Plasticity," by A. Nádai, McGraw-Hill Book Company, Inc., New York, N. Y., 1931, chap. 20.

[3] An explanation along somewhat similar lines, making use of torsion analogies for elastic and plastic torsion, has been advanced by Reuss. See *Zeitschrift für angewandte Mathematik und Mechanik*, 1938, p. 347.

specimen, but by the discontinuous behavior of the material around the yield point. As this discontinuous behavior of the material (visualized by a break in the stress-strain curve) is a fundamental attribute of the yielding process, it is not surprising that localization of flow resulting from instability seems also to be quite a characteristic phenomenon in yielding.

Explanation of Radial Growth of Plastic Regions

Fig. 3 represents a cross section of a round bar in torsion with a semicircular notch cut in its edge. We know from the theory of elastic stress concentrations that the stress is greatly increased at the inner edge of the notch, at *b*, and is greatly decreased at the sides of the notch, at *mm*, in comparison to other parts of the cross section at the same radius, or in comparison to what would occur if there were no notch.

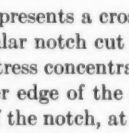

Fig. 3

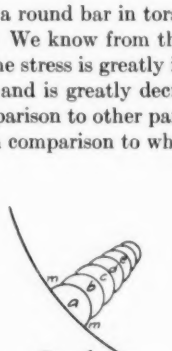

Fig. 4

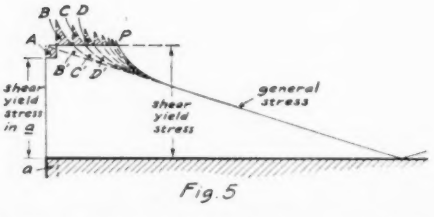

Fig. 5

These changes in the stresses at *b* and *mm* are obviously due to the elimination of the material of the notch. However, it is just as correct to say that it is due to the elimination of the *forces* which would otherwise be carried by the material of the notch, and which this material would transmit to the material outside the notch, because, obviously, the material of the notch has no effect on the material outside except through the forces it exerts on it.

Now, if the total elimination of these forces causes a large increase in stress at *b* and decrease at *mm*, then a partial elimination of the forces due to any cause will produce a proportionately smaller change in the stresses at *b* and *mm*. To put it in another way, instead of thinking of the elimination of these forces, we can think of counteracting forces being applied to the system. If such counteracting forces of a certain magnitude produce a certain result, i.e., a certain change in the stresses at *b* and *mm*, then, by the principle of superposition or linearity of action, counteracting forces of a fraction of that magnitude will produce the same fraction of the changes at *b* and *mm*.

Thus, since we know that complete elimination of the material of the notch increases the stress at *b* and decreases it at the corners *mm* by 100 per cent,[4] we can conclude that a 5 per cent decrease in the resistance of the material, and hence of the forces, taken by it and exerted by it across its boundaries, will cause about a 5 per cent increase of stress at *b* and decrease at *mm*. These changes will be much greater if the notch is elongated in the radial direction, instead of being of semicircular shape.

The formation of radially growing plastic regions in torsion can then be explained as follows: As the torsion increases, yielding first occurs at some region of local relative weakness such as must inevitably exist. Then the lagging of the stress in this yielded region relative to surrounding parts causes a stress redistribution around the region (of the same nature as if the region were a notch or hole, but of lesser magnitude) which retards stresses and therefore yielding in the tangential direction and accelerates them in the radial direction, thus leading to the elongation of the plastic region in the radial direction.

Considering this process in more detail, imagine that the material in a small region *a*, Fig. 4, is 5 per cent weaker—due perhaps to unfavorable orientation of the crystals—than the surrounding material. The material in this region will start to yield when the stress at the circumference reaches 95 per cent of the yield point. When the torsion is increased, the stress around this region will increase, but the stresses taken by and transmitted by the material within the region will remain substantially unaltered, assuming for simplicity that the material has a sharp yield point with a horizontal stress-strain curve after yielding.

When the stress has about reached the yield point on the circumference far from this region, there is therefore the equivalent of an elimination of about 5 per cent of the stress inside the region. This elimination would cause a rise in stress at *b* and a drop in stress at *mm* of 5 per cent, more or less, depending upon the shape of region *a*. But the stress at *b* was already nearly at the yield point, so that, with this increase, the stress in region *b* would have to be considerably greater than the yield point, and that at *c* just about at the yield point.

This is the condition which elastic theory indicates, i.e., a condition which satisfies equilibrium and continuity conditions everywhere. But the material cannot stand such a stress at *b* and will consequently yield, thus upsetting equilibrium again. This yielding is equivalent to an elimination of stresses in the region *b* of an amount equal to the excess they would otherwise have over the yield point. Thus, stresses have really been eliminated not merely over region *a* but over region *a* and *b* combined (which incidentally is a more pointed region than *a* alone, and hence causes a greater factor of stress concentration). This combined elimination of stress would require increased stresses at *c* for equilibrium, but again equilibrium is prevented because *c* was already at the yield point and its stress cannot increase. This amounts to a reduction of stress over *c* from the value required for equilibrium, which means that stress eliminations have occurred over *a*, *b*, and *c* combined, a still more pointed region. This leads to the yielding of regions *d*, *e*, etc., in succession.

Fig. 5 shows graphically the stress distribution along a radius passing through the region of original weakness, *a*. Area *A* indicates the stress reduction, below that otherwise required for equilibrium, which is due to the original weakness. Areas *B* and *B'* indicate the stress increase which this reduction would require, under elastic conditions, to maintain equilibrium. Area *B* represents a further stress reduction beneath what is required for equilibrium, due to yielding. Areas *C* and *C'* represent the stress increases due to this reduction, etc.

Actually, of course, the entire process would take place continuously instead of by steps. It might be described as a spreading of the plastic region (started by the original small weakness) toward the center in an effort to attain equilibrium, which is thwarted, for a time at least, by the continued yielding of the material under the influence of stress concentration. This self-perpetuating, or unstable, process will reach a definite end at some point such as *P*, Fig. 5, where, due to reduction in the general stress with the distance from the center, the sum of the general stress and stress increase is no longer above the yield

[4] "Strength of Materials," by S. Timoshenko, second edition, part 2, D. Van Nostrand Company, Inc., New York, N. Y., 1941, p. 325.

point. As the general stress is raised by increasing torsion, however, this point will move inward toward the center.

It should be emphasized that this explanation does not require that the material be weaker than normal anywhere except in the starting region, which can evidently be very small. Such minute points of weakness are bound to be distributed all over the cross section. The first yielding is naturally most likely to occur in one of the spots which is on or near the circumference, because the general stress is a maximum there. However, if yielding should first occur at an inside point, the yielded region would spread outwardly as well as inwardly, by the same process of reasoning as outlined. Such points of weakness act only as the initial disturbance or fuse which is necessary to *start* any unstable action, whereas after once being started the action is self-perpetuating. Similarly a strut, subjected to a load slightly above the critical, requires a slight disturbance or initial eccentricity to start the buckling, after which it continues unaided.

Even Distribution of Plastic Regions

The foregoing reasoning shows why slender radial plastic regions develop. Another remarkable fact, which has been mentioned, is that the regions are quite uniformly distributed around the circumference, instead of being closely bunched in some places and spread out in others, as might be expected if the distribution were entirely accidental. The explanation for this can obviously be found in the fact that, as has been pointed out before, the stresses are reduced at the sides of a plastic region, points *mm* Fig. 4, at the same time they are increased at the inner ends. The regions on either side of a plastic region are thus protected regions, safe harbors from stress and strain, where new regions are much less likely to start than elsewhere.

As the torque, and hence the general stress, is increased, more and more radial plastic regions are bound to be started, but, due to the protected flanks around those which have started, new regions will tend to start as far away as possible, i.e., about half way between those which have come before. Obviously, this would lead to the evenness of distribution which has been noted.

Increase in Width of Plastic Regions

The third and final feature of the phenomenon which requires explanation is the fact that, as the torsion progresses, the plastic

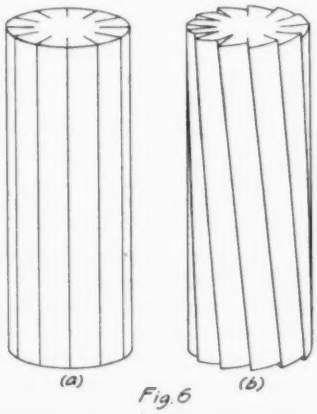

Fig. 6

regions gradually increase in width at the base or outside end. This fact seems to be directly opposed to the argument just cited, namely, that the stresses at the sides of the plastic regions are reduced, from which it might be expected that the plastic regions would remain narrow.

This widening of the plastic regions evidently represents a stabilizing tendency, which tends to change the unstable radial growth of Fig. 2, back toward the normal condition of Fig. 1, although it may never attain ascendancy over the unstable tendency as it does in the early stages of the tensile test. As in the tensile test, however, this stabilizing tendency is undoubtedly dependent upon the property of the material of strain-hardening after a certain amount of plastic flow has taken place. But in order to understand this fully, it will be necessary to consider more in detail the mechanism of the process.

Imagine a shaft in which a number of narrow radial slots have been cut, as shown in Fig. 6 (*a*). When this shaft is twisted it will present an appearance like Fig. 6 (*b*), the material between the slots undergoing very little distortion, while the sides of each slot slide relative to each other an amount which increases with the radius. The distortion of a shaft having plastic areas in the cross-sectional view, such as shown in Fig. 2 (*b*), must be similar to this. The plastic regions take the place of the slots, except that each plastic region will probably actually consist of numer-

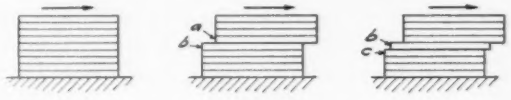

Fig. 7

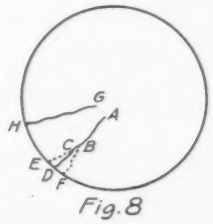

Fig. 8

ous surfaces each of which slides only a small part of the total. In any case, little distortion will take place in the unyielded material between the plastic regions, while large shear strains, increasing as the radius, will occur in the plastic regions.

After these shear strains reach a certain magnitude, the material which has been yielding stiffens up. If the relative sliding motion of the mass of the material on either side of the yielded region continues, then new planes of sliding must occur, say on either side of the stiffened material. Thus, the yielded region is widened. Fig. 7 illustrates such a process. A pile of plates is subjected to shear, sliding at first occurring between plates *a* and *b*. Due to heat of friction this surface seizes and plate *b* is dragged along with the top of the pile, creating a new sliding surface between *b* and *c*.

However, it is still not clear why the new sliding surface should occur next to the seized one, in preference to anywhere else. From the illustration, Fig. 7, it is apparently just as easy for it to occur next to the seized surface as anywhere else, but no easier. This does not conflict with what has previously been said regarding the reduction of stress at the sides of a yielded region. This reduction of stress is due to the *yielding* of the material in the region, but, as soon as this yielding ceases (as by stiffening of the material), the reduction of stress, and hence the immunity of material at the sides, ceases also.

If the stiffening of material due to strain-hardening occurred simultaneously all over the original surfaces of plastic flow, then there probably would be no reason for new surfaces to appear close to the old surfaces, and hence no explanation of the widening of the plastic region. But such simultaneous stiffening would be extremely unlikely. It is obvious that in practice stiffening will usually occur first at the outermost part of the sliding surface, where the relative motion is a maximum.

Assume for simplicity that there is only one original sliding surface in each plastic region, as in Fig. 6 (*b*) (the argument will be equally valid if there are many to start with, as would be probable). In Fig. 8 line *ABCD* shows the trace of such a surface in a cross-sectional view. Sliding proportional to the distance from the center occurs over this entire surface, and finally portion *CD* of the surface reaches the strain-hardening stage and in effect seizes. What happens then?

It seems obvious that a surface combining the still relatively weakened portion *ABC* with some new surface such as *CE*, will offer less resistance than an entirely new surface, such as *GH*. Or, to put the matter in a quite different way, after *CD* hardens, the surface *ABC* is still a plastic region, acting partially like an elongated hole, as discussed before, and causing stress concentration at both ends, *A* and *C*. Hence there is a strong tendency for the region to grow radially from *C*, and this growth will occur, not along the hardened path *CD*, but along some softer path such as *CE*. Similarly surface *BCE* will eventually harden, because all the outer sliding is now concentrated in it, leading to the formation of new surfaces, such as *BF*, etc. Thus plastic regions tend to widen at their outer ends, as well as to spread inwardly.

It is interesting to note that this is a process somewhat analogous to the case of a silt-carrying river, flowing over a gently sloping plain. When a portion of the original channel *CD* becomes choked with silt (strain-hardening), a backing up, or rise of water (stress concentration) occurs at *C*, leading to the formation of a new channel such as *CE*, etc., until we have a picture which is familiar in our geographies as that of many rivers at their mouths.

General Case—Formation of Lüders' Lines and Narrow Plastic Regions in Direction of Maximum Shear

In the case just considered it was found that the unstable localization of plastic flow was due to the tendency of an original sliding or shearing plane to spread laterally (that is, perpendicularly to the direction of sliding or of the shearing stress), under the influence of a concentration of shear stress of the type familiar to us in the case of twisted bars having discontinuities in their cross sections.

This sort of stress concentration is not confined to torsion specimens but will be produced whenever for some reason sliding or shearing starts locally. Fig. 9 shows such a case. Sliding has started in the vertical direction on surface *AA*, under the influence of vertical shearing forces and due, perhaps, to an initial crack or local weakness. A concentration of shear stress will be produced along the side of the surface, at points such as *p*, tending to make the surface spread horizontally in the direction of the dotted line, in exactly the same manner as in the torsion specimen Fig. 6 (*b*).

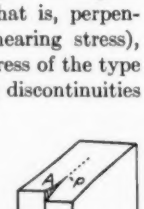

Fig. 9

This accounts for the spreading in the *lateral* direction of surfaces of sliding which start at minute points of weakness. However, it can easily be shown that a somewhat similar concentration of shear stress occurs at the *ends* of local sliding surfaces, which tends to make such surfaces spread in the direction of the sliding or of the shear stress, by exactly the same process as has been discussed.

Fig. 10 shows a portion of a body which is subjected to shear stress τ_0 and which contains an elliptical hole, with semiaxes *a* and *b*, in the directions of maximum shear stress. Intuition tells us that, if such a hole is elongated so that it approaches a crack, as shown in Fig. 10, there must be a high concentration of shear stress at points near the end of the crack, such as at *p*, while the shear stress will be nearly zero at the sides of the crack, as at point *q*. Intuition tells us this in spite of the fact that we know the shear stress must be zero exactly at the edge of the hole.

This case is included in Inglis' well-known study of the effect of elliptical holes,[5] although neither Inglis nor anyone else has apparently paid any attention to the concentration of *shear* stress at points such as *p*, perhaps because this stress is zero at the edge of the hole, and consequently it is not immediately apparent that a high stress concentration may exist just beyond the edge. From a previous paper[6] of the author's, containing a generalization of Inglis' work, it can be shown that the shearing stress τ, along the axis of symmetry a distance xa from the center of the hole, is

$$\tau = \frac{rx[r^2x^2(r^2+1) - (r^2+2)(r^2-1)] - 2r(r^2x^2 - r^2 + 1)^{3/2}}{(r^2x^2 - r^2 + 1)^{3/2}\,(r-1)^2}\,\tau_0 \qquad \ldots [1]$$

where $r = a/b$ is a measure of the slenderness of the hole.

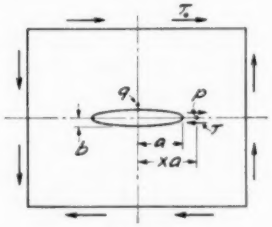

Fig. 10

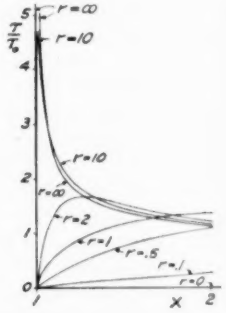

Fig. 12

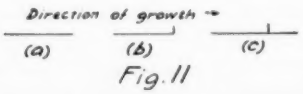

Fig. 11

Fig. 12 shows values of the shear stress concentration τ/τ_0, calculated from Equation [1], for various values of the slenderness r and the relative distance from the edge of the hole x. It can be seen that as the slenderness increases the stress concentration also increases, and its maximum value occurs closer to the edge of the hole, although the stress always comes down to zero at the edge itself (at $x = 1$). For $r = 10$, that is, for a hole 10 times as long as it is wide, a stress concentration of 4.7 occurs at a distance of about $0.01a$ from the edge. For $r = \infty$, that is, for a crack, there is an infinite stress concentration right at the edge of the hole; in this case the edge of the hole is a singular point where the stress concentration has values of both zero and infinity, depending upon whether the point is approached from the left or from the right. In the other direction, when r is small, the stress becomes very small near the hole; this evidently corresponds to the condition at points such as *q* in the middle of the broad side of the hole.

It now seems clear why surfaces of sliding, starting at minute points of weakness, tend to grow or spread, not only in the lateral direction, but in *all* directions along the surfaces of maximum shear stress. Sliding first starts, naturally along the direction of the surface of maximum shear stress, at some point where the resistance to sliding is less than in surrounding regions. As

[5] "Stresses in a Plate Due to the Presence of Cracks and Sharp Corners," by C. E. Inglis, Trans. Institution of Naval Architects, vol. 55, part 1, London, 1913, pp. 219–230.

[6] "Stress Concentrations Due to Elliptical Discontinuities in Plates Under Edge Forces," by L. H. Donnell, Theodore von Kármán Anniversary Volume, California Institute of Technology, Pasadena, Calif., 1941, p. 305.

the external loads increase, the shear resistance on this small yielded surface remains about constant, while the shear stresses increase elsewhere. By the time the stresses elsewhere have risen to the shearing yield point, there is the equivalent of the removal of a certain amount of internal resistance along the yielded surface.

Complete removal of this resistance would be equivalent to the existence of a crack, which would require for equilibrium large increases in the shear stress all around the periphery of the yielded surface, due to one or the other of the two types of stress concentration which have been discussed. Partial removal of the resistance requires proportionately smaller increases in the shear stress for equilibrium. The required increases cannot occur, because the material is already at the yield point and yields, so the yielded region has to spread yet further in search of equilibrium. At each stage of the process the surface which has already yielded forms a partial crack which tends to raise the stresses, and hence causes yielding, just beyond its borders.

As the yielded surface grows, it will tend to follow the original surfaces of maximum shear, because the combination of the original shear stress plus the increases due to stress concentration will obviously tend to be greater in that direction than in any other direction. There are, of course, at every point in a stressed body two mutually perpendicular surfaces of maximum shear. Since the shear stresses on these surfaces are equal it might be supposed that a yielded surface, in its growth, would find it just as easy to branch off at right angles at any point as to continue along the original surface in which it happened to start.

Actually, however, there is probably rather a strong tendency for it to continue along the original surface rather than to branch off, because the stress concentration at the end of a crack or partial crack of the shape shown in Fig. 11 (*a*) is probably higher than when the shape is as in Fig. 11 (*b*). Growth such as shown in Fig. 11 (*a*) tends to lengthen the original crack, and hence to increase the stress concentration. On the other hand, growth such as in Fig. 11 (*b*) probably has much the same general effect as widening the crack, and hence reducing the stress concentration. Thus, if such branches occur, growth along them will be slower than along the original direction. When the yielded region reaches the stage shown in Fig. 11 (*c*) growth along the branch path will tend to stop entirely because the whole branch will be in the protected zone at the side of the main crack.

How far such surfaces will grow will depend upon the variation in the general stress along the surface of maximum shear. When the general stress is uniform, as in a tensile specimen, so that the general stress is just about at the yield point everywhere before the growth starts, the sliding surfaces will grow completely across the entire specimen during a very slight change in the external load. Or, if the material is of the type which has an upper and a lower yield point, it is conceivable that they would spread explosively across the specimen without the external load changing at all.

When the general stress varies from point to point, as in torsion, bending, and around discontinuities, the sliding surfaces will, of course, tend to start at the most highly stressed points and spread until they reach a point where the decreased general stress plus the increase due to stress concentration is no longer above the yield stress. This will happen while the external loads are increasing only the slight amount necessary to balance statically the small localized increases in stress which this process entails. As the external loads increase, the yielded surfaces will, of course, also increase.

Similarly, the tendency to even spacing of yielded regions and the fact that they widen after considerable straining has occurred can be explained by the reduction of stress at the sides of yielded surfaces, strain-hardening, etc., for the general case in the same manner as for the twisted bar. It is believed that this discussion makes clear the mechanism of formation of Lüders' lines, which are the traces or intersections with the external surface of the yielded surfaces or narrow yielded regions, as well as all the other evidences which we have[7] that plastic flow tends to localize in narrow regions following the lines of maximum shear stress.

It can now be seen that the twisted bar first discussed is only a special case of the general phenomenon. There are some points in that case which we can now see in a somewhat different and clearer light. It was assumed previously that the region of starting weakness had the shape of a "notch cut in the edge" of a cross section. In order to produce the stress concentrations assumed, such a weakness would have to run the full length of the bar, or at least be considerably elongated in the direction of the length.

It is evident now that sliding will start on planes of maximum shear, such as an axial plane, at a point of weakness near the outer surface, and progress longitudinally by virtue of stress concentrations of the type of Fig. 10. The longitudinal surfaces of sliding thereby formed, will then spread in the radial direction in the manner originally discussed. We thus finally arrive at the spreading of the original sliding surface in all directions along maximum shear planes, as in the general case.

Moreover, the round shape which was assumed for the sake of the argument for the initial region of weakness can now be seen to have been unnecessarily pessimistic. Whatever shape the region of weakness may have, sliding will first start on surfaces of maximum shear. It is these sliding surfaces, having a shape to produce very high stress concentrations, which are the real starting point of the process.

Etching of sections of twisted bars seldom seems to reveal the presence of yielded surfaces in the circumferential direction.[8] There seems to be no ready explanation for their not forming as easily as longitudinal surfaces, unless it may lie in the "grain" or anisotropy of manufactured bars.

Discussion

Equiareal Pattern of Stress Trajectories in Plane Plastic Strain[1]

C. W. MacGregor.[2] A method is described in the paper by which the principal stress trajectories can be determined from their equiareal properties. These principal stress trajectories are very valuable in the analysis of any plastic-flow problem. We have approached the problem of their determination from the experimental point of view. The flow layers, which appear during early plastic flow, have been observed by a special equipment,[3] called a "plastiscope," in many problems such as: The cold-rolling of metals; the yielding of butt and lap welds; the plastic flow present in rollers compressed laterally; rivet holes punched in plates; and in many cases of stress concentration produced by notches, holes, etc. This equipment has been designed with considerable flexibility in mind. It can be applied equally well to the observation and recording of plastic flow in such cases as the rolling of metals, machining of metals, experiments in various testing machines, etc. In most cases motion pictures are made of the plastic flow as it is produced in each process; however, still photographs can also be made.

Having determined the pattern of flow layers experimentally in this manner, the principal stress trajectories can then be constructed easily from their property of cutting the family of flow layers at 45 deg.

It appears that the method described in the paper should be useful in supplementing and checking the method of construction outlined.

Modern Passenger-Car Ride Characteristics[1]

R. W. Brown.[2] The motorcar engineer has done an excellent job on the mechanical units of today's passenger cars. Possibilities for significant improvement appear to exist in working out the dynamic conditions which promote passenger comfort, decrease fatigue, and thereby increase safety.

The authors are to be congratulated for a concise, clear presentation of the complex performance of the various elastic and inertia elements of the car which are set into action when the wheel passes over even a single wave of simulated road inequality. Such articles provide a foundation for the statistical study of the thousands of vibrations to which the passenger is subjected in even a short ride.

The importance of "secondary" vibration has long been known to the ride engineers. Some recent research work[3] has been completed which emphasizes the importance of the seat cushion in isolating the passenger from uncomfortable effects of such vibrations. In a recent article,[4] dynamic performance of seat cushions was presented. Thus, a complete picture of the dynamic performance of the most important elastic systems of the motorcar under single-wave or repeated cyclic conditions has now been presented in the literature.

The Riding Comfort Research Committee of the Society of Automotive Engineers is active in encouraging and correlating efforts to the end that next year's motorcars will provide the passenger a constantly increasing freedom from the uncomfortable and fatiguing conditions incident to vibration, irrespective of its source. This work has substantiated the authors' contentions regarding mathematical analysis, importance of secondary vibrations, axle tramp, and interrelation of displacement and acceleration in bounce, pitch, and roll. The disclosure of axle motion is important, and their comment on rate of change of acceleration is interesting. It would appear that technical knowledge of suspension performance has received another worth-while addition.

Transient Torques in Induction-Motor Drives[1]

E. L. Davis.[2] Computations made by us from the data presented by the author indicate that couplings *A*, *B*, *C*, *D*, *E*, and *F* are separate and distinct designs of well-known manufacturers. We recognize coupling *E* as a Falk "steelflex" coupling.

After reviewing this paper, we agree that of all the couplings tested *A*, *B*, and *C* are properly applied on this particular drive. A coupling of the *E* type can be selected to give similar results. Obviously the coupling of the *E* type tested was not properly selected. The nonlinear torque-deflection characteristic of the type *E* coupling was not the cause of its undesirable effect on this drive. This coupling did not function properly because of its high average torsional-stiffness factor of 1,270,000 lb-in. per radian when compared to the low stiffness factors of couplings *A*, *B*, and *C*.

Table 1, herewith, shows the author's data in bold face and our calculations in regular face. The calculations shown in regular face were made from data shown in bold face, with the stiffness factor of the connecting shafts assumed to be 189,000,000 lb-in. per radian. Calculation gave 372,000 lb-in. per radian as the stiffness factor of coupling *D*. It was impossible to check the author's stiffness factors assigned to couplings *A* and *C* when working back from the frequencies he tabulated. Data, in Table 1, in regular face were also partly based upon the proportions of design that $I_r/(I_m + I_r) = 0.91$ and that $I_r = 10 \times I_m$ as stated by the author; where I_r = moment of inertia of roll, and I_m = moment of inertia of gear motor rotor, referred to the low-speed shaft.

NOMENCLATURE

K = stiffness factor, lb-in. per radian
f_n = natural frequency of systems, cycles per sec
f = electrical frequency, cycles per sec
T_m = peak torque, lb-in.
T_s = motor starting torque, lb-in.
T_s' = motor starting torque referred to low speed, lb-in.
T_p = motor plugging torque, lb-in.
T_p' = motor plugging torque referred to low speed, lb-in.

We agree with the author that for his test drive, which duplicates an existing roll-table drive at a steelmill, the ratio of $\frac{\text{natural frequency}}{\text{electrical frequency}}$ or f_n/f should be less than 0.6. For this reason couplings *A*, *B*, and *C* were successful for 60- and 40-cycle motors and not so successful for 20-cycle motors for this particular drive. By proper selection of coupling *E*, with the average stiffness factor the same as the constant stiffness factors of either couplings *A*, *B*, or *C*, coupling *E* will be suitable for this drive. In other words, it is possible to select a size and type *E* coupling having a ratio of f_n/f = 0.284 for 60 cycles.

This paper is helpful in showing conditions of stiffness factor for which a coupling should be selected or designed. Coupling *E* would have been ideal for certain mass-elastic systems of run-out tables other than those chosen for test comparison.

In design it is sometimes impossible to obtain proportions of f_n/f less than 0.6 due to space limitations or construction costs. When these items enter into the problem, one may be forced to select a design with proportions of f_n/f equal to 2 or greater. In this case coupling *E* as selected for the author's test would definitely be a better selection than couplings *A*, *B*, or *C* although none of the four would be adequate in capacity to transmit the peak torques. Fig. 1,[3] submitted with this discussion, shows that coupling *C* at 20 cycles with ratio of f_n/f = 0.9 (Table 1) will be in the range of resonance, whereas, coupling *E* will be beyond the range of resonance with a ratio f_n/f of 1.88.

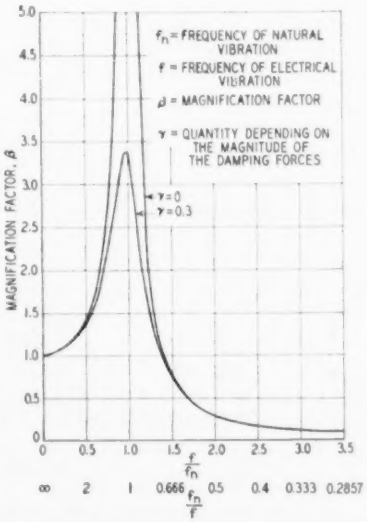

FIG. 1 CURVES SHOWING COUPLINGS WITHIN AND BEYOND RANGE OF RESONANCE

It is noteworthy that 55 couplings of type *E* have been successfully operating on run-out tables for 10 years on a 20-in. and 30-in. mill of a well-known steel company without mechanical failure. At another large steel mill, there are 486 type *E* couplings on run-out tables. A third steel mill reports excellent service from 25 type *E* couplings on run-out tables at the 84-in. hot-strip mill.

AUTHOR'S CLOSURE

Replying to Mr. Davis' discussion, the author would like to mention that the primary object of the paper has been to give designers a means of calculating the shaft torques set up in typical induction-motor drives during starting; the comparison of the results obtained by using various couplings was made primarily as a check on the method of calculation. The author agrees with the discusser that coupling *E* would not be satisfactory for an actual drive having the characteristics of the test drive. It was included as one of the test couplings in order to show how the shaft torque may be increased as a consequence of impact effects due to nonlinearity in the torque-angle characteristic of the coupling. It is clear that these impact effects could be greatly reduced by using a larger coupling of the *E* type such that the torque-angle curve would be practically linear for torques within the operating range.

Mr. Davis states: "The nonlinear torque-deflection characteristic of the type *E* coupling was not the cause of its undesirable effect on this drive. The coupling did not function properly because of its high average torsional-stiffness factor of 1,270,000 lb-in. per radian when compared to the low stiffness factors of

[3] "Vibration Problems in Engineering," by S. Timoshenko, second ed., D. Van Nostrand Company, Inc., New York, N. Y., 1937, p. 41.

couplings *A*, *B*, and *C*." Presumably the reasoning behind this statement is that this high stiffness factor tends to produce resonance. However, referring to Fig. 9 of the paper, the oscillogram obtained on coupling *E* shows a tendency toward resonance only at 20 cycles where the peak torque occurred on the second cycle; at 40 and at 60 cycles there is a sharp peak on the first cycle which is characteristic of an impact condition. For this reason the author believes that the high torque observed at 60 and at 40 cycles when using this type *E* coupling is due primarily to impact effects augmented by coupling nonlinearity and is only in part due to the relative stiffness of the coupling. At 20 cycles there is a combination of effects due to coupling nonlinearity and resonance which also results in relatively high torques. The author does agree, however, that conditions would be considerably improved as far as the test drive is concerned by using a type *E* coupling having the same average stiffness factor as for couplings *A*, *B*, or *C*. It should be noted that the average stiffness factor for a nonlinear coupling of this type increases with the applied torque, so that the peak torque must be specified if the average stiffness figure is to have meaning.

The values for natural frequencies f_n as given in Table 1 of the paper for couplings *A*, *B*, *C*, and *D* are approximate values obtained from actual oscillograph records. It was considered that this method would probably yield more accurate values than calculations based on the torque-angle curves as obtained from static tests on the couplings. The figures of 80,000 to 120,000 lb-in. per radian, given in the paper for the rubber-element couplings, were average values obtained by static torque-deflection tests. Under dynamic conditions it is quite possible that these stiffness values would be higher as indicated by the discusser.

Referring to Table 1 of the discussion, values of T_m/T_s were obtained by the author as follows: The nominal values of T_m/T_s for a load of infinite inertia were first found for the given values of f_n/f (or ω_n/ω) and locked power factor cos ϕ. Since the load inertia was not infinite these values were then corrected to take this into account by multiplying by $I_r/(I_m + I_r) = 0.91$ as mentioned in the paper. Thus for coupling *A* at 60 cycles, $f_n/f = 0.233$, cos $\phi = 0.52$, $T_m/T_s = 2.7$, assuming case (*b*) with infinite load inertia. Multiplying this by 0.91 gives a round figure of 2.5 for finite-load inertia. The discusser has evidently obtained the locked power factors given in his Table 1 by using the author's values of T_m/T_s and f_n/f in Figs. 4 and 5 of the paper without making this correction. In addition, the curves given in these figures are not plotted to a sufficiently accurate scale to enable this to be done accurately. This accounts for the differences shown in Table 1 between the discusser's values of locked power factor and those given by the author; the latter figures were based on actual electrical tests on the motor with the rotor locked.

It is suggested by the discusser that in cases where, due to space limitations or expense, a design with f_n/f less than 0.6 is not practical, a figure of f_n/f equal to 2 or greater be used. However, the author would like to point out that even where this is done, peak torques several times the nominal starting torque T_s may still occur depending upon the electrical characteristics of the motor. The reason for this is that, if f_n/f is high, i.e., if the shaft is very stiff, it may be expected that the peak shaft torque will be practically equal to the peak electrical torque acting on the rotor. This electrical torque in turn may be several times T_s, depending upon the locked power factor cos ϕ. It is shown elsewhere[4] that, for high-resistance motors of the type usually employed in this service, the peak electrical torque T_s (for nonsimultaneous voltage application on all phases) is given approximately by

$$T_s = T_s\left(1 + \frac{\sqrt{2}}{\cos\phi}\right) \quad \text{[1]}$$

For simultaneous voltage application the factor $\sqrt{2}$ is replaced by unity. Using Equation [1] and assuming a locked power factor of 0.5, the electrical torque becomes $T_s = 3.83\ T_s$, and as mentioned previously if f_n/f is very large this will also be the shaft torque.

Where f_n/f is not large (but yet considerably greater than unity so that damping may be neglected) a solution could be obtained for linear systems as follows: The expressions for transient electrical torque given by Equations [2] and [3] of the paper are taken in the differential equation for the system, Equation [7]. This equation is then solved using the proper boundary conditions. It will be found, however, that this method leads to considerable complication and for this reason the following approximate method may be used.

It may be shown that for high-resistance rotors of the type usually employed for this service, the term $\epsilon^{-\lambda_2 t}$ in Equation [3] of the paper dies out very rapidly during the first cycle of applied voltage, while for the usual motor with high magnetizing reactance the term $\epsilon^{-\lambda_1 t}$ may be taken as unity for several cycles of the applied voltage. Hence as an approximation (for nonsimultaneous voltage application) the electrical torque given by Equation [3] of the paper may be considered essentially as a constant torque T_s on which is superimposed an alternating torque at the electrical frequency f equal to $\frac{\sqrt{2}}{\cos\phi}\ T_s$. This alternating torque will be subject to a magnification as indicated by the discusser's Fig. 1. Neglecting damping this magnification is given by $1/[1 - (f/f_n)^2]$. Thus for $f_n/f = 2$ the magnification factor will be 1.33 and the alternating torque $\frac{1.33\sqrt{2}\ T_s}{\cos\phi}$. As an example for cos $\phi = 0.5$ the peak shaft torque then becomes $T_m = T_s\left(1 + \frac{1.33\sqrt{2}}{\cos\phi}\right) = 4.78\ T_s$. If a 20-cycle motor, having a locked power factor of 0.87 is used, the peak torque will be reduced to $T_m = T_s\left(1 + \frac{1.33\sqrt{2}}{0.87}\right) = 3.17\ T_s$ for the same ratio f_n/f. If there is some coupling nonlinearity an additional increase in torque may be expected. These examples show that torques of considerable magnitude may exist even if f_n/f is made 2 or larger.

The author wishes to take this opportunity to thank Mr. Davis for his contribution and interest in the problem.

Analysis of Longitudinal Motions in Trains of Several Cars[1]

L. H. Fry.[2] This paper is an interesting contribution to the information available for analysis of the relative longitudinal motions of the individual cars in a railroad train. It is to be hoped that the author will be able to extend his method so that it may bring into account the friction action of the draft gears and the effect of slack between the couplers. The equations given in the paper are based upon cars connected by springs having uniform spring characteristics throughout closure and release.

[1] By W. M. Dudley, published in the December, 1941, issue of the Journal of Applied Mechanics, Trans. A.S.M.E., vol. 63, p. A-145.

[2] Railway Engineer, Edgewater Steel Company, Pittsburgh, Pa. Mem. A.S.M.E.

In reality the draft gears connecting the cars are designed to close and to release against relatively high friction. This is a vital element of draft-gear design. In every draft gear approved by the Association of American Railroads, the energy given up on release is less than 40 per cent of that put in during compression. This being the case, it is obvious that the wave of energy transmitted along the train will be damped rapidly and the wave reflected from the end will be very much less than is indicated in Figs. 6 and 7, in the paper.

The author suggests that the slack in the couplers between the cars will not come into play unless the amplitudes of vibration build up to several inches. In practice, any slack between the couplers must be alternately pulled out and taken up again during each cycle of vibration in which the draft gear goes from closure in buff to closure in pull.

It may also be pointed out that the numerical examples in the paper cover only five cars. In railroad work, the problems of practical interest involve trains of 100 cars or more. It appears that the direct application of the author's method to a 100-car train would lead to a group of Equations [14], involving 100 equations each containing 100 terms. The work involved in developing and then solving any such group of equations would be prohibitive.

O. R. Wikander.[3] To the writer's knowledge this is the first exact mathematical analysis which has been published, covering the action of an elastic chain, consisting of concentrated masses connected by frictionless springs. His use of the little-known "difference equations" for this purpose is also very interesting.

In his introductory remarks, the author compares his elastic-chain method with the known elastic-bar method and states that the results in his paper tend to show that the wave velocity in an elastic chain is only about two thirds of that in an equivalent elastic bar. We feel that this statement is misleading and that, on the contrary, the author's investigations tend to show that both methods give practically the same speeds of wave propagation.

The first example in the paper refers to a five-car train, represented by five concentrated, equal masses, connected by four identical frictionless springs.

The left-hand car approaches the rest of the train at a given speed and is coupled on, causing a speed-and-pressure wave to pass through the train.

In Figs. 2 and 3 of the paper, the car displacements and the velocities of the individual cars, as computed according to the author's method, are plotted against time.

Referring to the curves in these figures, the author points out that, according to the elastic-bar method, the wave would travel one car length in 1 time unit, while Fig. 3 shows a travel of one car length in 1.4 time units. This time is computed from the travel of the crest of the velocity wave, which is the resultant of a number of waves of different speeds, and thus continually changes its shape. If, instead, the author had measured the time interval between the moment when car No. 1 had moved the relative distance of one unit, until car No. 5 had moved the same distance, he would have found that exactly 4 time units had elapsed, showing a perfect agreement with the wave speed, as computed by the elastic-bar method.

In case of a seven-car train, the elastic chain would have 6 natural frequencies.

If the author's matrix method were used in solving the resulting difference equations, excessive time would be required to compute the displacements of all the cars.

For trains of more than ten cars, the amount of computation necessary when the author's method is used is so formidable as to appear prohibitive.

It is probable, however, that the method can be simplified and, at the same time, extended so as to apply to a wider field. This seems worth while, even if such simplifications should give only approximate, but truly comparative, results.

Fig. 10 in the paper is of particular interest. Curve A shows the velocity of wave travel at the lowest, curve B at the highest, natural frequency of trains consisting of from 2 to 45 cars.

Because of the great internal friction in the draft gears of any modern train, all higher harmonics will be effectively damped out, and it appears permissible to disregard all but the lowest natural frequency, represented by curve A. It will then be found that the velocity of wave travel increases from 90 per cent of that of an elastic bar in a two-car train to 95 per cent in a three-car train and to 100 per cent in any train of twelve cars or more.

In closing, the writer expresses the hope that the paper is only the beginning of the author's work in the comparatively virgin field of train dynamics.

Author's Closure

Messrs. Fry and Wikander both point out that the amount of calculation required to solve train problems by difference equations would be prohibitive if the train included more than about ten cars. This is implied in the title of the paper. It is true that for a train of 100 cars, the equation of motion of each car would contain 100 terms. It would probably not be necessary to compute the equations except for a few cars at important points of the train.

However, as Mr. Fry points out, such a solution would not be valid, owing to energy absorption in the draft gears. It seems unlikely that an exact solution will ever be calculated for problems involving slack or dry friction between cars. Both of these effects are mathematically discontinuous, that is, all the equations of the entire problem would have to be adjusted every time one pair of couplers reached the end of slack, or reversed its direction of relative slip. Furthermore, with dry friction, slip does not begin until the tension changes by a definite amount. It can be seen that it would take years to solve a problem involving a few cars, under these conditions.

If slack were eliminated and friction of the dashpot type (proportional to velocity) assumed, solutions could be obtained quite easily, as in long-distance telephoning problems, where the resistance of the line is included.

The writer does not agree entirely with Mr. Fry's comment that slack must inevitably come into play during vibrations. If the train is running, each pair of couplers carries the steady pull necessary to overcome running friction of the cars behind. Thus the vibrations are superposed on an average tension. Unless the compressive force of vibrations exceeds this tension, backlash or slack cannot occur.

Mr. Wikander's comments on the velocity of wave travel are interesting. It appears that the value found for this velocity will vary, depending upon whether one observes the times when cars first begin to move, when they have their maximum velocity, or when they have moved a definite distance.

In conclusion, it may be repeated that the paper is aimed at dynamic problems of short trains, such as passenger trains, involving not more than a dozen cars. For 100-car freights, it will probably always be necessary to distribute mass, stiffness, friction, and slack uniformly along the train, as is done in Mr. Wikander's well-known paper.[4] The author wishes to thank Messrs. Fry and Wikander for their encouragement and the discussions based on practical experience.

Note on Angular Motions of Ships[1]

H. O. Fuchs.[2] The author mentions the controversy involving the type of coupling between tank and ship. The question was whether the system had force coupling or inertia coupling.

Recently it has been shown[3] that the type of coupling (force or inertia) is not a characteristic of the physical system, but depends upon the arbitrary choice of co-ordinates. The same system (e.g., ship tank or double pendulum) will show force coupling with one set of co-ordinates and inertia coupling with another set. The controversy between Frahm and Schuler was without point; they were both right, but used different systems of co-ordinates. The various co-ordinates lead of course to the same result; their choice is a matter of convenience. Coupling by damping is inherently different by its phase. In undamped systems it is always possible to choose the natural modes as co-ordinates; the coupling then disappears from the equations; in damped systems, the coupling can be eliminated from the equations only under special conditions.

It follows that coupled systems cannot be classified by the type of coupling. Classification by invariant characteristics has been studied by Quade.[4]

Author's Closure

Mr. Fuchs has raised an interesting point which requires a far more extensive analysis than can be given here.

The situation which Mr. Fuchs mentions is created by the fact that the coupling terms appearing in the differential equations of a coupled system arise as the result of application of the Lagrangian equations to the systems. If, therefore, the latter equations are omitted and the differential equations with coupled terms are written by *a priori* considerations, as is usually done in the technical literature, one finds difficulty in attaching to these terms a definite physical interpretation, in so far as they do not stand in any direct relation with the fundamental invariants of the system; such as the law of energy, for example.

The matter gains in clarity, however, if instead of writing the differential equations with coupling terms introduced more or less *a priori*, one goes through a more laborious procedure of forming the Lagrangian equations. In so doing, one is obliged to form the expressions for the kinetic and potential energies of the system. The former is generally obtained without any particular difficulty. As to the latter, it requires an appropriate choice of the system of reference which is generally imposed by the problem itself.

In order to clarify this point, the following example will make apparent the underlying physical nature of the dynamical phenomena involved:

Consider a physical pendulum to which is attached a horizontal track in the plane of oscillation of the pendulum; on this track may roll a weight with negligible friction; the weight may be displaced by a cable driven by a motor.[5] It can be assumed that this cable passes through the axis of oscillation so that the inertial coupling, as usually defined, is negligible. Under these assumptions there is neither inertial nor frictional coupling provided in the system, comprising the pendulum and the weight. Assume that we control the motion of the weight as follows.

The weight arrives at the end of the track just at the instant when this end begins to rise in space owing to the motion of the pendulum and is kept there (e. g., by means of a catch) until this end reaches its maximum height. At this moment the catch is released, the weight slides "downhill," and the same phases are reproduced for the opposite swing.

Experiment shows that the motion of the pendulum is damped in such case (assuming that it was undamped with the weight fastened to its track).

The results are the same if the motion of the weight, instead of being discontinuous, is continuous of the form $x = k\,\theta$, where x is the departure of the weight from the middle of the track, $\dot{\theta}$ the angular velocity of the pendulum, and k a factor of proportionality.

It is easier, however, to discuss qualitatively the discontinuous arrangement.

The explanation of this phenomenon is very simple. The system in this case is conservative by our assumption. Since the weight is kept at the end of the track which is rising in space, the gravity performs a negative work, in so far as the weight always moves against the gravity. The work is thus absorbed and is converted into the potential energy of the raised weight. However, this absorption of energy can occur only at the expense of the diminution of the kinetic energy of the pendulum which, in fact, is observed since the amplitudes of oscillation decrease. The subsequent transfer of the weight downhill occurs at the expense of the potential energy so gained, but this has no effect on the pendulum in view of the fact that, in the arrangement described, the weight has neither potential nor frictional coupling with the pendulum.

One is tempted, therefore, to consider the coupling in this case as a kind of force coupling following Schuler's classification.

From the preceding explanation, it appears that the expression "potential coupling" is perhaps more appropriate. Furthermore, the following point of importance is to be noted: The increase of potential energy occurs with respect to the external field of force, i.e., the gravity ("Fernwirkung" using Klotter's term) and has nothing to do with the internal forces set up in the system itself.

These considerations can be easily generalized for the liquid-ballast transfer in a system of tanks. The only delicate point which arises in this case is the expression of the potential energy. This requires a particular choice of co-ordinates subordinated to Schuler's criterion, viz., there is no potential coupling between the ship and the ballast in a passive tanks system. In fact an inclination of the ship (θ_0) does not "incline" the free level in tanks in a steady-state condition. If, however, instead of the absolute level, one introduces the relative level φ_0 in tanks, the Schuler condition of passive tanks requires that $\theta_0 + \varphi_0 = 0$. Starting from this point, it is possible to express the potential energy of the system in terms of both parameters θ and φ and then form the Lagrangian equations. There appear no further ambiguities in this formulation in so far as the choice of co-ordinates is not arbitrary any more but becomes subordinated to the physical end of the problem.

The principal difficulty which Schuler encountered seems to be in the fact that, having established a correct criterion differentiating the passive performance of tanks from the active one, he came back to the differential equations with coupled terms instead of going through the formation of the Lagrangian equations, and thus found himself again in a vicious circle.

From this standpoint, Klotter's suggestion of building up the *actio in distans* theory is particularly interesting; it is then possible to use the Lagrangian equations, provided the expression of the potential energy is expressed in suitable co-ordinates, as has been explained.

The advantage of this procedure lies in the fact that it deals directly with the physical entities (the energies) of the system, so that the choice of suitable co-ordinates instead of being arbitrary becomes imposed by these physical considerations.

Book Reviews

Torsional Vibration

PRACTICAL SOLUTION OF TORSIONAL VIBRATION PROBLEMS. By W. Ker Wilson. Second edition, John Wiley & Sons, Inc., New York, N. Y. Cloth, 6 × 9 in., Vol. 1, 1940, xx and 731 pp., 110 figs., $8; Vol. 2, 1941, xxi and 694 pp., 237 figs., $8.50.

REVIEWED BY GEORGE B. KARELITZ[1]

A single-volume edition of this book appeared in 1935. The second edition reflects the spectacular progress achieved during the intervening years in the field of general and torsional vibration. The author lists among others: A more general application of tuning mechanical oscillating systems, in order to place severe critical zones either above or below the operating speed ranges; the accumulation of data relating to fatigue phenomena; the introduction of the rotating pendulum vibration-absorber in aircraft engines; the investigation of the oscillating aero engine—air-screw system as a whole; the introduction of flexible mountings for engines and instruments; the study of "nonlinear" vibration systems.

All this new material, together with the author's desire to utilize a large amount of new practical design data, doubled the subject matter of the book and made the second edition a more valuable source of information for those who are working practically with torsional vibrations. The work can hardly be classified as a textbook in vibration and it does not intend to be. The reader should be familiar with the general elementary theory of vibration before undertaking the author's two volumes.

But these will be rather helpful as a means to translate the general principles into practical engineering forms. They are particularly timely at present, when so many engineers are concerned with torsional vibrations in plane, ship, or tank engines. The text is illustrated by frequent practical examples, with solutions worked out to final numerical values. Schemes to facilitate numerical computations are indicated in many instances. Useful and convenient tables of empirical design data are given, such as the comparative torsional stiffness of crankshafts of various designs. Valid physical approximations are suggested; for instance, the reasonable mass allowance is given for inertia of the water entrained by a vibrating marine propeller.

The book consists of twelve chapters, six in each volume, with appendixes to each volume. Chapter 1 recapitulates the relations governing the frequency of torsional vibration in systems with one degree of freedom. It shows also the approximate handling of systems with two, three, or more masses. Chapter 2 discusses the methods and arrangement of calculation for the natural frequency, for multimass systems in marine, automotive, and aviation machinery. Chapter 3 gives the torsional rigidities of practical crankshafts and the equivalent mass inertias of various details of engine installations, such as gears, propellers. A special chapter, the fourth, is devoted to the rigidity and design of flexible couplings. Chapter 5 treats the reduction of a geared system to an equivalent single shaft with several masses; the handling of gear transmissions used in aircraft is given particular attention. Chapter 6 deals with the determination of stresses at nonresonant speeds, i.e., torsional amplitudes in crankshafts. The effects of the number of cylinders and the firing order in engines of the in-line, vee, and radial types are discussed in detail.

Chapter 7 discusses stresses due to torsional vibration at resonant speeds and the effect of damping. Empirical numerical data are given on damping in commonly encountered designs of both engines and driven elements, as well as on the internal damping of structural materials. The permissible working stresses and the effect of stress concentration are indicated. Chapter 8 describes the design and operation of many commercial instruments for measuring torsional vibrations, while chapter 9 shows how to analyze and interpret records obtained by means of the torsiographs. Chapter 10 describes vibration-damping devices, for use with internal-combustion engines; numerous illustrations of vibration absorbers and friction dampers are given together with the theory of their action. Special importance is attached to the rotating-pendulum vibration absorber, in chapter 11. Designs of this device and their operation are discussed in detail. Chapter 12 gives the dynamic characteristics of electrical generating sets direct-coupled to internal-combustion engines, their torsional vibrations, governing, and flywheel effect.

The two volumes will be of assistance to mechanical engineers who are dealing with torsional vibration in their daily activity. The books will also be of interest to students of the science of vibrations, in bringing together many practical problems awaiting more rigorous solutions. Selected bibliographies at the end of each volume and detailed indexes add to the value of the book as a source of reference.

Principles of Mechanics

PRINCIPLES OF MECHANICS. By J. L. Synge and B. A. Griffith. First edition. McGraw-Hill Book Company, Inc., New York, N. Y., 1942. Cloth, 6 × 9 in., xii and 514 pp., 162 figs., $4.50.

REVIEWED BY CHARLES W. MACGREGOR[2]

THE authors have stated their object in the preface as follows: "In a sense this is a book for the beginner in mechanics, but in another sense it is not. From the time we make our first movements, crude ideas on force, mass, and motion take shape in our minds. This body of ideas might be reduced to some order at high school (as crude ideas of geometry are reduced to order), but that is not the educational practice in North America. There is rather an accumulation of miscellaneous facts bearing on mechanics, some mathematical and some experimental, until a state is reached where the student is in danger of being repelled by the subject, as a chaotic jumble which is neither mathematics nor physics. This book is intended primarily for students at this stage. The authors' ambition is to reveal mechanics as an orderly self-contained subject."

This single volume treats the usual elementary subjects of statics, kinematics, and dynamics, but in addition covers the more advanced topics of vibration, kinematics, and dynamics in space together with a short chapter on the special theory of relativity. The scope of the book is therefore much broader than the usual text in this field which either treats only the more elementary phases of the subject or else, taking these for granted, embarks

[2] Associate Professor of Applied Mechanics, Massachusetts Institute of Technology, Cambridge, Mass. Mem. A.S.M.E.

on an extensive development of the more advanced subjects. The authors have also adopted a distinct departure in their division of the subject matter. They have elected to divide the treatment into plane mechanics and mechanics in space. In each of these parts, the subject of statics, kinematics, and dynamics are discussed separately. This means that the subject of statics in three dimensions is left until the subjects of kinematics and dynamics in the plane are disposed of. The customary procedure in the past has been to complete the treatment of both two- and three-dimensional statics before embarking on motion problems.

The mathematical background of the authors is well reflected in their attention to mathematical rigor, and even the most meticulous would feel quite satisfied on this score.

At the end of each chapter summaries are given of the more important formulas and conclusions developed, a procedure which has been adopted in too few cases in the past by authors on this subject. This enhances the value of the book greatly both as a text and as a reference work.

The first three chapters are devoted to a discussion of the equilibrium conditions in plane statics with applications to friction problems, thin beams, cables, and frames. In the development of the theory both the principle of virtual work and the parallelogram law are used in different places as basic premises. In the discussion of bending moments and shearing forces in beams it will be noted that the sign of the shearing force is taken opposite to the customary convention in this country. The treatment of cable problems is perhaps more rigorous than that appearing in many elementary texts since it is based on the differential equation rather than resorting to a "freezing technique" together with the three-force theorem.

Chapters 4 to 8 cover the subject of plane kinematics and dynamics with applications to the motion of projectiles with and without air resistance, vibration problems with and without damping, planetary orbits, plane motion, and impulsive motion.

Chapters 9 to 15 discuss mechanics in space, including statics, kinematics, and dynamics with applications to space frames, the spherical pendulum, the motion of a charged particle in an electromagnetic field, the spinning top, and gyroscopes. In chapter 15 Lagrange's equations are developed and applied to such problems as the determination of the normal frequencies of vibration of a system with two degrees of freedom, etc.

The special theory of relativity is discussed briefly in chapter 16. The Lorentz transformation connecting the co-ordinates of a pair of Galilean observers and the equations of motion in relative form are treated.

The very breadth and scope of the subject, encompassed as in this case in a single volume, has necessitated perhaps a somewhat briefer discussion of the various parts than is customary for engineering students in this country. The average engineering student who does not possess more than the commonly required undergraduate mathematical background also might experience some difficulty in certain portions of the book. This refers especially to the use of vector analysis in the discussion of mechanics in space. While many of the applications and examples given illustrate the theory very ably, the engineer might prefer less academic and more practical problems as illustrations. The authors have also preferred to omit any discussion of graphical methods used so generally in engineering practice. In spite of this, however, the book represents a very comprehensive exposition of the subject; and while it may be found to be most useful as a text in the education of mathematics and science students, or for a survey course for the more advanced engineering students, it is quite evident that many practicing engineers will find this volume a very welcome addition to their own reference libraries.

High-Pressure Plant and Fluids at High Pressure

THE DESIGN OF HIGH-PRESSURE PLANT AND THE PROPERTIES OF FLUIDS AT HIGH PRESSURES. By Dudley M. Newitt. The Oxford University Press, New York, N. Y., 1940. Cloth, 6¼ by 9½ in., viii and 491 pp., tables, diagrams, plates, $10.

REVIEWED BY JOSEPH H. KEENAN[3]

IN these busy days when the current professional literature waiting to be read piles higher and higher, and that Saturday afternoon when other things will not be pressing seems more and more remote, a book like this one should be warmly welcomed. It presents in 500 pages and in coherent form the literature of the experimental attack on the properties of fluids at elevated pressures.

In the preface the author states that, "In view of the rather specialized nature of the subject, it has been thought advisable to emphasize the experimental aspect and to devote several chapters to the design of high-pressure plant and to the methods of measuring high pressures." And so we find discussion of elastic and plastic properties of metals and the effects on these properties of the presence of gases under high pressure. Then comes a good chapter on devices for measuring pressures of magnitudes up to thousands of atmospheres.

The major part of the book is given over to a discussion of the properties of vapors and liquids at pressures that are high relative to the critical pressure. It requires no more than a limited acquaintance with this subject to appreciate the diligence and skill that has gone into the compilation and presentation of this material. It is generously illustrated with a fascinating collection of figures drawn largely from the literature. References are numerous and complete.

The disturbed state of the world will not readily permit the patient thorough work necessary to the preparation of a book of this sort. We shall, therefore, prize more highly those that have reached the stage of publication.

von Kármán Anniversary Volume

IN the review of this volume in the March issue of the JOURNAL it was stated in the first paragraph that Clark Millikan was the editor of this volume. This was an error since the volume was the work of friends of Theodore von Kármán, as stated in the heading of this particular review.

Torsional and Flexural Buckling of Bars of Thin-Walled Open Section Under Compressive and Bending Loads

By J. N. GOODIER,[1] ITHACA, N. Y.

The observed behavior of torsionally weak columns in buckling by twisting rather than, or as well as, bending is analyzed in this paper on the basis of a hypothesis due to Wagner. The theory is simplified, and extended to the general section, where results simpler than some already obtained by Kappus are given. It is further extended to bars, restrained by flexible sheets, and bars with constrained axes of rotation. Wagner's hypothesis is applied to the problem of lateral buckling, where it yields the accepted theory for symmetrical sections, but indicates results of novel form for unsymmetrical cases. Similar results are obtained in the problem of eccentric thrust, whatever the section.

Introduction

THE ordinary Euler buckling of a compressed bar does not always occur when the section is torsionally weak. Instead the bar may buckle by twisting, or by a combination of flexure and twist. It is easy to see how the purely flexural deformation, assumed in the Euler theory, can be maintained by bending moments of the thrust created by the deformation itself, but it is somewhat difficult to see how a torsional deformation can be maintained by thrust, in the general case.[2] In the special case of the angle section, such buckling may be explained by regarding each leg as a plate, as was done in 1910 by Timoshenko (1).[3] An analysis for the arbitrary open section was made by Wagner on different lines (2, 3), involving a tacitly assumed hypothesis, describing the torsional effect of the thrust. This hypothesis is adopted here, where it is used to obtain equations more general than Wagner's (which include further unessential assumptions and approximations), and more simple than those of Kappus (4), who replaced Wagner's hypothesis by an equivalent energy hypothesis, also employed here. Kappus' theory introduces two new constants of the section (R_x, R_y) which are found to be unnecessary. They do not appear when advantage is taken of certain properties of the shear center.

The theory of buckling by torsion and flexure under simple thrust is thereby given a simpler form than hitherto. It is extended to the case of a stiffener attached to a perfectly flexible sheet, which permits displacement of the line of attachment normal to it, but not parallel to it. Such a fundamental solution might be made the basis of a method of predicting the strength of stiffened panels, by including in the effective section the equivalent width of sheet indicated by a formula such as the well-known one of von Kármán.[4] Use of a stiffener section, augmented by von Kármán's effective width of sheet, in the Euler formula is current in aircraft design, but this of course takes no account of torsional effects.

The hypothesis of Wagner is further applied to the theory of lateral buckling, or buckling under bending loads, where it indicates that the present theory, due to Prandtl, Michell, and Timoshenko, will be inadequate except in special cases. In his original paper (2), Wagner considered the bar under eccentric thrust, attributing buckling entirely to the torsional effects of the thrust. The same problem, however, formed a part of the older theory of lateral buckling where it was attributed entirely to the bending moment of the eccentric thrust. The two effects are quite distinct, and evidently a complete theory must include both. This paper constitutes an attempt to do this, with various explicit results for critical loads in important special cases.

A fuller account of the subject is given in references (6) and (7).

Arbitrary Thin-Walled Section—Uniform Thrust

Buckling of the bar is taken to occur by twisting and bending deformations. The buckled form is specified by components of displacement, u, v of the shear center of the cross section, and a torsional rotation β about the shear center. The axe of x and y, Fig. 1, are taken with the origin at the shear center S, and directions, unless otherwise stated, parallel to the principal

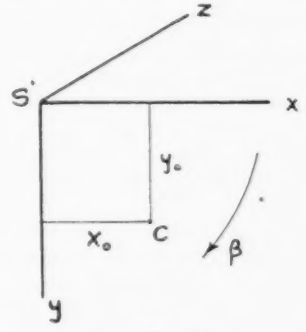

FIG. 1

axes of the section at the centroid. The z axis is the axis of shear centers.

It has been shown (6) that nonuniform torsion (the torsional moment varying along the bar) occurs by relative rotation of cross sections about the axis of shear centers (in the uniform tor-

[1] Professor of Mechanics, Cornell University. Mem. A.S.M.E.

[2] Torsional buckling has sometimes been entirely attributed to noncoincidence of centroid and shear center, but this is inadequate since such buckling can occur when these points are coincident.

[3] Numbers in parentheses refer to the Bibliography at the end of the paper.

Presented at the Annual Meeting, New York, N. Y., December 1–5, 1941, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until October 10, 1942, for publication at a later date. Discussion received after the closing date will be returned.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

[4] A method of this type, based on Wagner's formula for the torsional critical load of an unattached bar was proposed by E. E. Lundquist and C. M. Fligg: "A Theory for Primary Failure of Straight Centrally Loaded Columns," N.A.C.A. Technical Report No. 582, 1937.

sion of the Saint Venant theory the location of the axis of relative rotation is immaterial), and that the torsional moment M is given in terms of the rotation β of the section z by

$$M = GC\beta' - E\Gamma\beta''' \quad [1]$$

(primes denoting differentiation with respect to z) where GC is the Saint Venant torsional rigidity, G is the shear modulus, E is Young's modulus, and Γ a constant defined (6) in terms of the cross-sectional warping of the Saint Venant theory. This is a generalization of a similar relation obtained for the I-section by Timoshenko.[5] It was derived by Wagner (2).

Thus when the deformation u, v, β occurs, u produces bending stress forming a moment EI_1u'' in the x, z plane; v produces a moment EI_2v'' in the y, z plane, and β an axial moment as given by (1). I_1 and I_2 are the usual (centroidal) moments of inertia.

The stress on a cross section, besides forming the moments just discussed, must form a horizontal force P to balance the applied thrust P on the end. The former, being the resultant of

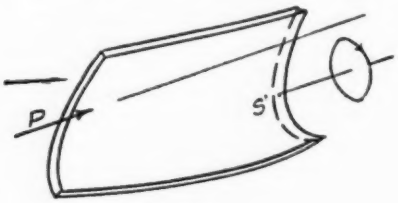

FIG. 2

uniform compressive stress only infinitesimally disturbed by the buckling, acts at the centroid of the displaced section. The components of displacement of the centroid are $(u - y_0\beta)$, $(v + x_0\beta)$, x_0 and y_0 being the co-ordinates of the centroid. The forces P, acting on the piece of the bar between the left end and the section z, thus form a couple $P(u - y_0\beta)$ in the x, z plane, $P(v + x_0\beta)$ in the y, z plane, the centroid of each end being undisplaced, and we have the equations (corresponding to the Euler theory)

$$EI_1u'' + Pu - Py_0\beta = 0 \quad [2]$$

$$EI_2v'' + Pv + Px_0\beta = 0 \quad [3]$$

The formation of a third equation requires Wagner's hypothesis. This presupposes that the stress on the cross section consists of the fiber stress—the fibers being of course inclined to the z axis—which is, except for small additions due to the deformation, simply uniform compression, σ, together with the (small) shearing stress of nonuniform torsion forming the moment [1]. There is also the shearing stress of bending, with resultant through the shear center.

Consider the moment, formed by the stress on the section, about an axis through the displaced shear center, but parallel to the z axis. The fiber stress σ forms a force σdA, on an element of area dA which, in virtue of the inclination of the fiber to the axis, has a moment of the type just defined of

$$\sigma dA\ [y(u' - y\beta') - x(v' + x\beta')] \quad [4]$$

in the sense of the curved arrow in Fig. 2. The total moment formed in this way is

$$Py_0u' - Px_0v' - P\rho^2\beta' \quad [5]$$

where P is written for σA, and ρ is the polar radius of gyration of the section about the shear center.

The moment formed by the shear stress of nonuniform torsion is given by [1], except perhaps for the cosine of a small angle as a factor, which is unimportant.

The shear stresses, associated with the bending, form no moment of the type in question since their resultant passes through the shear center. Thus moments [1] and [5] together must form zero moment so that

$$E\Gamma\beta''' + (P\rho^2 - GC)\beta' - Py_0u' + Px_0v' = 0 \quad [6]$$

Sections With Coincident Centroid and Shear Center

This case includes sections with two axes of symmetry, and sections with "point symmetry" such as the Z-section with equal flanges. Then $x_0 = y_0 = 0$ and Equations [2] and [3] become the usual Euler equations for buckling in the principal planes. Equation [5] becomes

$$E\Gamma\beta''' + (P\rho^2 - GC)\beta' = 0 \quad [7]$$

with the general solution

$$\beta = C_1 \cos kz + C_2 \sin kz + C_3$$

where

$$k^2 = (P\rho^2 - GC)/E\Gamma$$

A bar to which thrust is applied by ball joints, centered at the centroid of each end, would have the end condition $\beta = 0$ at $z = 0$, to eliminate rigid-body rotation. It is also necessary to have β'' at $z = 0$ and $z = l$, l being the length of the bar, since, as has been shown (6), nonuniform torsion involves an axial stress proportional to β''. It may be readily verified that these three conditions can only be satisfied if $kl = n\pi$ where n is an integer. This yields

$$P = \frac{1}{\rho^2}\left(GC + \frac{n^2\pi^2}{l^2}E\Gamma\right) \quad [8]$$

for the critical thrusts corresponding to modes

$$\beta = C_2 \sin n\pi z/l$$

C_2 remaining arbitrary. This is Wagner's critical thrust for torsional buckling. When it is less, with $n = 1$, than both the Euler critical thrusts, buckling will occur by twisting rather than bending.

This discussion does not exhaust all conceivable types of solution of Equation [7], but it has been shown (6) that the others have slight practical significance.

For fixed ends, the middle half of the bar will correspond to the solution given.

Sections With One Axis of Symmetry—Arbitrary Sections

The axis of symmetry being the x axis, $y_0 = 0$ and Equation [2] becomes the ordinary Euler equation. The critical thrust π^2EI_1/l^2 may be derived from it. However, Equations [3] and [6] are simultaneous equations in v and β, indicating that the other two modes of buckling are neither purely flexural nor purely torsional. A solution in the form $v = C_2 \sin n\pi z/l$, $\beta = C_3 \sin n\pi z/l$, corresponding to rotatable ends, leads to the critical condition

$$\begin{vmatrix} 1 - \dfrac{Q_n}{P} & x_0 \\ x_0 & \rho^2\left(1 - \dfrac{T_n}{P}\right) \end{vmatrix} = 0$$

where

$$Q_n = \frac{n^2\pi^2\,EI_2}{l^2}, \quad T_n = \frac{1}{\rho^2}\left(GC + \frac{n^2\pi^2}{l^2}E\Gamma\right)$$

[5] Bibliography (1), p. 256.

This quadratic yields

$$\frac{1}{P} = \frac{1}{2}\left\{\frac{1}{Q_n} + \frac{1}{T_n} \pm \sqrt{\left(\frac{1}{Q_n} - \frac{1}{T_n}\right)^2 + \frac{4}{Q_n T_n} \cdot \frac{x_0^2}{\rho^2}}\right\}$$

and it may be shown that one of the values of P is less than the smaller of Q_n, T_n, while the other exceeds the greater of Q_n, T_n.

For the arbitrary section, a solution of Equations [2], [3], and [6], as they stand, may be taken in the form

$$u = C_1 \sin\frac{n\pi z}{l}, \quad v = C_2 \sin\frac{n\pi z}{l}, \quad \beta = C_3 \sin\frac{n\pi z}{l}$$

corresponding to rotatable ends. The condition of consistency of the equations in C_1, C_2, C_3 obtained by substitution is the cubic in $1/P$

$$\left(1 - \frac{P_n}{P}\right)\left(1 - \frac{Q_n}{P}\right)\left(1 - \frac{T_n}{P}\right) - \left(1 - \frac{P_n}{P}\right)\frac{x_0^2}{\rho^2} - \left(1 - \frac{Q_n}{P}\right)\frac{y_0^2}{\rho^2} = 0$$

P_n being $n^2\pi^2 EI_1/l^2$. The lowest critical load will normally correspond to $n = 1$.

Bar Attached to Flexible Sheet

The attachment to the sheet, Fig. 3, imposes the condition $u - h\beta = 0$ all along the bar. If the bar is first imagined free, and buckled so that this condition is not fulfilled, as it would not be in general, forces must be applied in the plane of the sheet, to nullify the x displacement along the line of attachment.

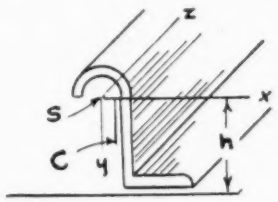

Fig. 3

These forces will exert both flexural and torsional actions. They are easily included in the differential equations, reference (6). The result of the calculation is that buckling of the form

$$u = hC_3 \sin\frac{n\pi z}{l}, \quad v = C_2 \sin\frac{n\pi z}{l}, \quad \beta = C_3 \sin\frac{n\pi z}{l}$$

can occur if the thrust P satisfies the quadratic

$$\left(1 - 2\frac{y_0}{h} + \frac{\rho^2 - x_0^2}{h^2}\right)P^2 - \left[P_n + \left(1 - 2\frac{y_0}{h} + \frac{\rho^2}{h^2}\right)Q_n + \frac{\rho^2}{h^2}T_n - 2\frac{x_0}{h}R_n\right]P + Q_n\left(P_n + \frac{\rho^2}{h^2}T_n\right) - R_n^2 = 0 \quad [9]$$

Here the axes x, y are no longer parallel to the principal axes through the centroid, but parallel and normal to the sheet, and $R_n = n^2\pi^2 EI_{12}/l^2$ where I_{12} is the product of inertia for axes through the centroid parallel to the x, y axes.

Ramberg, McPherson, and Levy (5) found stresses, at failure, in the Z-stringers of their test panels as given in Table 1.

TABLE 1 STRESSES AT FAILURE IN Z-STRINGERS OF TEST PANELS

	Sheet thickness 0.070 in.			Sheet thickness 0.025 in.			
Length, (fixed ends), in.	19	7.26	11.62	19	19	19	19	19
Stringer stress at failure, psi	36200	36400	37400	38400	31300	30200	30400	36200

From the dimensions given in their paper, the Euler critical stresses (for fixed ends, 19 in. length) work out to 27,400 and 176,000 psi, and the Wagner critical stress, Equation [7], for torsional buckling to 37,500 psi. The critical stresses obtained from the quadratic Equation [9] (with $l = 9.5$ in., $n = 1$), corresponding to attachment to a perfectly flexible sheet, are 31,600 and 157,000 psi. The lower value conforms to the observed values for the thinner sheet, and being close to the proportional limit of the material requires little if any correction on that score.

To take account of the stiffness of the sheet, an effective width of sheet, acting with the stiffener to form an augmented section, might be determined from von Kármán's formula, or an equivalent, and the critical stress redetermined from Equation [9].

If the section has an axis of symmetry normal to the perfectly flexible sheet, one possible mode of buckling is the ordinary Euler buckling by flexure in the plane of symmetry, unhindered by the sheet. The other mode, involving twisting, with bending parallel to the sheet, has the critical load

$$\left(P_n + \frac{\rho^2}{h^2}T_n\right) \Big/ \left(1 - 2\frac{y_0}{h} + \frac{\rho^2}{h^2}\right)$$

The value for a section with two axes of symmetry, normal and parallel to the sheet, is obtained by putting $y_0 = 0$.

Enforced Axis of Rotation

If the bar is constrained along a given axis, parallel to it, as by frictionless hinging, or its equivalent, the stability can be investigated by considering the forces exerted by the hinge when buckling occurs, or by the energy method (6). If the coordinates of the given axis are $x = a$, $y = b$, we have $u - b\beta = 0$, $v + a\beta = 0$, all along the bar. There is only one type of buckling, involving rotation of the cross sections about the hinge axis, and the critical load is found to be

$$\frac{GC + \frac{n^2\pi^2}{l^2}(\Gamma + I_1 b^2 + I_2 a^2 - 2I_{12}ab)}{a^2 + b^2 + \rho^2 - 2ax_0 - 2by_0}$$

Loading by Thrust, Bending, and Twisting

This more general problem is illustrated by Fig. 4. In addition to the thrust P, applied at the centroids of the end sections,

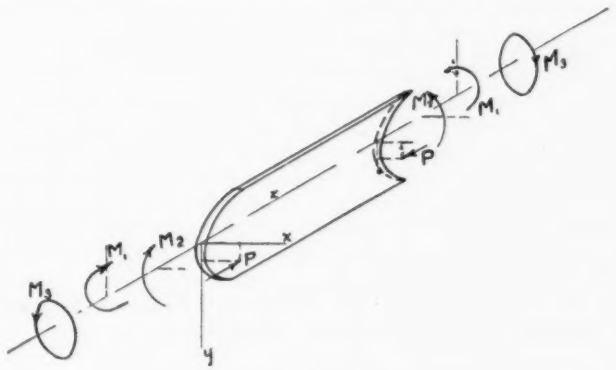

Fig. 4

and corresponding to uniform compression, the bar is bent by end couples M_1 in the x, z plane, M_2 in the y, z plane, and twisted by the torsional couple M_3. Thus the configuration of the bar, even if stable, involves flexure and torsion. In Fig. 5, which represents the piece of the bar between the left end and the section z, moments are represented by vectors. M_u and M_v

are the (bending) moments formed by the stress on the section. The torsional couple formed by the stress is omitted. The axes ξ, η are the displaced x, y axes of the section z. The equations of the type $\Sigma M_\xi = 0$, $\Sigma M_\eta = 0$ are

$$EI_1 u^{v} + Pu + M_3 v' + (M_2 - Py_0)\beta = -M_1 \ldots [10]$$

$$EI_2 v^{v} + Pv - M_3 u' - (M_1 - Px_0)\beta = -M_2 \ldots [11]$$

The x, y axes are here parallel to the principal centroidal axes.

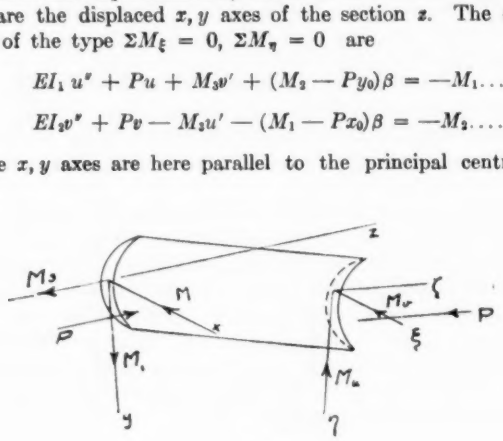

FIG. 5

The third equation is again obtained by taking moments about an axis through the shear center of the displaced section z, and parallel to the original axis of the bar. The compressive fiber stress is now, to a sufficient accuracy

$$\frac{P}{A} - \frac{M_1}{I_1}(x - x_0) - \frac{M_2}{I_2}(y - y_0)$$

When this is used in place of σ in [4], and the total moment computed by integration, we obtain instead of [5]

$$-P(x_0 v' - y_0 u' + \rho^2 \beta') + M_1\left(v' + \frac{\kappa_1}{I_1}\beta'\right) - M_2\left(u' - \frac{\kappa_2}{I_2}\beta'\right)$$

where

$$\kappa_1 = \int x(x^2 + y^2)\, dA - x_0 A\rho^2, \quad \kappa_2 = \int y(x^2 + y^2)\, dA - y_0 A\rho^2$$

The equation under consideration is thus found to be

$$E\Gamma\beta''' + \left(P\rho^2 - GC - M_1\frac{\kappa_1}{I_1} - M_2\frac{\kappa_2}{I_2}\right)\beta' + (M_2 - Py_0)u' - (M_1 - Px_0)v' = M_3 \ldots [12]$$

Equations [10, 11, 12] are three simultaneous equations for u, v, β which may be solved to determine the equilibrium configuration under the given loads, whether this is stable or not. To investigate the stability, let U, V, B be these equilibrium values, and let $(U + u_1)$, $(V + v_1)$, $(B + \beta_1)$ represent a neighboring configuration. Then u_1, v_1, β_1 satisfy Equations [10, 11, 12] with the right sides zero. These "stability" equations reduce to the simpler forms derived by Timoshenko[6] (with differences of sign accounted for by the different choice of axes) if we put $\Gamma = P = M_1 = M_3 = 0$ and take the section as doubly symmetrical, so that $x_0 = y_0 = \kappa_1 = \kappa_2 = 0$. The terms with $P\rho^2$, κ_1, κ_2 in Equation [12] appear to be new and result from Wagner's hypothesis.

Buckling Under Pure Bending

For this case we put $P = M_3 = 0$. A solution of the stability equations may be found in the form

$$u_1 = C_1 \sin\frac{n\pi z}{l}, \quad v_1 = C_2 \sin\frac{n\pi z}{l}, \quad \beta_1 = C_3 \sin\frac{n\pi z}{l} \ldots [13]$$

making the displacement and rotation vanish at $z = 0$ and $z = l$. On substitution, the condition that C_1, C_2, C_3 be different from zero is found to be

$$P_n M_1^2 + Q_n M_2^2 - P_n Q_n\left(\rho^2 T_n + M_1\frac{\kappa_1}{I_1} + M_2\frac{\kappa_2}{I_2}\right) = 0 \ldots [14]$$

As special cases we may consider the following:

Two Axes of Symmetry. Point Symmetry: On account of the symmetry

$$x_0 = y_0 = \kappa_1 = \kappa_2 = 0$$

and Equation [14] becomes

$$P_n M_1^2 + Q_n M_2^2 - P_n Q_n T_n \rho^2 = 0$$

For bending in one principal plane (y, z) only, $M_1 = 0$, and the critical bending moments are

$$M_2 = \pm\sqrt{P_n T_n \rho^2} \ldots [15]$$

which may be written

$$\pm\frac{n\pi}{l}\sqrt{EI_1\left(GC + \frac{n^2\pi^2}{l^2}E\Gamma\right)}.$$

For the I-beam this agrees with Timoshenko's result.[7]

One Axis of Symmetry. When this axis is normal to the plane

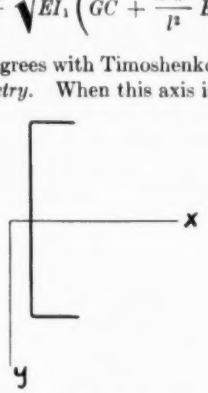

FIG. 6

FIG. 7

of bending, as in the channel section bent in the principal plane parallel to the web, Fig. 6, we have

$$y_0 = \kappa_2 = 0, \quad M_1 = 0$$

and again the critical moment is given by Equation [15].

However, if the axis of symmetry is in the plane of bending, as in the T-section, bent in the plane of the web, Fig. 7, we have $x_0 = \kappa_1 = 0$ and $M_1 = 0$, but

$$y_0 \neq 0, \kappa_2 \neq 0$$

Then Equation [14] becomes a quadratic for M_2 yielding

$$M_2 = \frac{1}{2}\left\{P_n\frac{\kappa_2}{I_2} \pm \sqrt{P_n^2\frac{\kappa_2^2}{I_2^2} + 4P_n T_n \rho^2}\right\} \ldots [16]$$

The positive sign yields a positive M_2 and the negative sign a negative M_2, whether κ_2 be positive or negative. Thus, the

[6] Bibliography (5), chap. 5.

[7] Bibliography (1), Equation [159], p. 261.

critical moment is different according as the beam is bent up or down. The quantity κ_2/I_2 as may be seen from the definition of κ_3 under Loading by Thrust, Bending, and Twisting, will be a length of the order of the over-all dimensions of the section. For a 90-deg-angle section with thin walls, κ_2/I_2 is $\sqrt{2}$ times the length of leg, the y axis being in the plane of symmetry. The quantity $P_n\kappa_2/I_2$ is of importance in Equation [16] if its square is comparable with $4\,P_n\,T_n\,\rho^2$ or if $(\kappa_2/I_2\rho)^2\,(P_n/4T_n)$ is comparable with unity. This is so if P_n and T_n are comparable, which is certainly the case for bars which are liable to buckle torsionally under thrust.

It may be shown that the fiber stress, corresponding to the moment [15] is of the order $\sqrt{P_1T_1/A^2}$ which will evidently be attainable when both P_1/A, T_1/A are within practical limits. This will be so for sufficiently thin-walled sections, or when the smallness of P_1/A compensates for largeness of T_1/A as in the thin rectangular section.

Other Loadings—Eccentric Thrust

The thrust is regarded as eccentric when its line of action, although parallel to the bar, does not pass through the centroids of the end sections. The components of eccentricity are e_1 and e_2 when the co-ordinates of the line of action are $(x_0 + e_1)$, $(y_0 + e_2)$. Then the eccentric thrust P is equivalent to a centroidal thrust P together with end moments M_1, M_2 equal to $-Pe_1$, $-Pe_2$, respectively. Using these values, and putting $M_3 = 0$ in Equations [10, 11, 12], a solution of the form [13] leads to the critical condition

$$\rho^2\left(1-\frac{P_n}{P}\right)\left(1-\frac{Q_n}{P}\right)\left(1-\frac{T_n}{P}\right)+\left(1-\frac{P_n}{P}\right)\left(1-\frac{Q_n}{P}\right)\left(\frac{e_1\kappa_1}{I_1}+\frac{e_2\kappa_2}{I_2}\right)-\left(1-\frac{P_n}{P}\right)(e_1+x_0)^2-\left(1-\frac{Q_n}{P}\right)(e_2+y_0)^2=0 \quad \ldots.[17]$$

the lowest of the three values of P being the critical load.

Two Axes of Symmetry. $x_0 = y_0 = \kappa_1 = \kappa_2 = 0$: The equation remains a cubic. However, if the line of thrust lies in a principal plane, say y, z, $e_1 = 0$ and the third term of Equation [17] disappears. One root is $P = Q_n$ corresponding to Euler buckling in the principal plane containing the thrust. There are two other types of buckling involving flexure and torsion at loads given by

$$\frac{1}{P}=\frac{1}{2}\left\{\frac{1}{P_n}+\frac{1}{T_n}\pm\sqrt{\left(\frac{1}{P_n}-\frac{1}{T_n}\right)^2+\frac{4\,e_2^2}{P_n\,T_n\,\rho^2}}\right\}$$

One of the values of P is less than the smaller of P_n, T_n the other exceeds the greater of P_n, T_n.

One Axis of Symmetry. Some simplification of Equation [17] occurs when the thrust is in the plane of symmetry. With the y axis as an axis of symmetry we have $e_1 = x_0 = \kappa_1 = 0$ and the reduced form of Equation [17] again yields $P = Q_n$ for one root. The others are the roots of the quadratic

$$\frac{1}{P^2}-\left(\frac{1}{P_n}+\frac{1}{T_n}+\frac{1}{T_n}\cdot\frac{e_2\,\kappa_2}{\rho^2 I_2}\right)\frac{1}{P}+\left[1+\frac{e_2\,\kappa_2}{\rho^2 I_2}-\frac{(e_2+y_0)^2}{\rho^2}\right]\frac{1}{P_n T_n}=0$$

The general problem can also be solved when the bar is attached to a flexible sheet, or has a constrained axis of rotation. The results are given in a current paper (7) by the author.

Distribution of Stress in Built-In Beams of Narrow Rectangular Cross Section

By F. B. HILDEBRAND[1] and ERIC REISSNER,[1] CAMBRIDGE, MASS.

This paper deals with the problem of the distribution of stress in cantilever beams of narrow rectangular flanged cross section with one end of the beam rigidly built-in. Since an exact solution of this plane-stress problem appears difficult to obtain, an approximate solution is derived by applying the principle of least work. Instead of the linear normal stress distribution of the elementary beam theory, a third-degree polynomial is assumed, and the spanwise variation of this stress curve is determined by means of the calculus of variations. Numerical results are obtained with regard to the stresses at the built-in end of the beam, in their dependence upon (*a*) the span-height ratio of the beam, (*b*) the flange area–web area ratio of the beam, (*c*) Poisson's ratio of the material, and (*d*) the distribution of load along the span. It is found that the deviations from the results of the elementary theory may be appreciable when the distance of the center of gravity of the load curve from the built-in end of the beam is less than twice the height of the cross section of the beam.

Introduction

IT IS well known that the distribution of stress in bent beams as given by the elementary theory, as well as by known solutions of the exact theory, does not in general satisfy exactly prescribed conditions of support at the ends of the beam. It is also known that such deviations are of appreciable influence on the stress distribution when the cross-sectional dimensions of the beam are not small compared with the span length of the beam. The problem of the exact determination of the stresses for prescribed conditions of support, when formulated as a boundary-value problem of the general equations of the theory of elasticity, is one of considerable difficulty which thus far has found no exact solution in many interesting cases. In some instances approximate solutions have been obtained by the application of minimum-energy principles.

It is the purpose of this paper to add new approximate solutions of interest to those now existing, by investigating the distribution of stress in cantilever beams of flanged narrow rectangular cross section, one end of each beam built-in and the other end free. Results are obtained concerning the deviations of the stresses from those given by the elementary theory in their dependence upon the following:

1 The span-height ratio of the beam.
2 The flange area–web area ratio of the beam.
3 The distribution of load along the span.
4 Poisson's ratio of the material.

To obtain these results the principle of least work is employed in a form which has recently been found effective for the solution of problems somewhat related to those under consideration (1).[2] As will be seen this form of the method has the advantage of being more flexible than those forms of the least-work method previously applied (2, 3, 4, 5), and also, in a certain sense, it leads to more accurate results.

Formulation of the Problem

The determination of the stress distribution in a beam of narrow rectangular cross section may be considered as a problem in the theory of plane stress. If a system of coordinates (x, y) is introduced, the direction of x coinciding with the direction of the axis of the beam, and the direction of y perpendicular to the x axis, then according to the elementary beam theory, the normal stress σ_x is a linear function of y, the shear stress τ a quadratic function of y, and the transverse normal stress σ_y a negligible quantity. It is well known that these assumptions do not satisfy exactly the equations of the theory of plane stress, except for the case of a cantilever beam with concentrated end load, and that, moreover, this distribution of stress implies conditions of support of the beam not always met with in reality. In particular, it is known that these assumptions, concerning the distribution of stress, imply expressions for the components of the displacement of the elements of the beam which do not permit originally plane cross sections of the beam to remain plane after the load has been applied. For example, one of the possible conditions of support which cannot be satisfied by such a solution is that of a rigidly built-in end. It is known that the distribution of stress in the neighborhood of such an end section which is restrained from warping may deviate appreciably from the one given by the elementary beam theory (5, 6). The following developments are principally concerned with the problem of determining these deviations in their dependence upon the various factors mentioned in the introduction.

Starting with the expressions for the beam stresses in terms of Airy's stress function

$$\sigma_x = \frac{\partial^2 \phi}{\partial y^2} \qquad \sigma_y = \frac{\partial^2 \phi}{\partial x^2} \qquad \tau = -\frac{\partial^2 \phi}{\partial x \partial y} \quad \ldots\ldots [1]$$

it is known that the stress-strain relations

$$\frac{\partial u}{\partial x} = \frac{1}{E}(\sigma_x - \nu\sigma_y) \qquad \frac{\partial v}{\partial y} = \frac{1}{E}(\sigma_y - \nu\sigma_x) \qquad \frac{\partial u}{\partial y} + \frac{\partial v}{\partial x} = \frac{1}{G}\tau \quad \ldots\ldots [2]$$

require ϕ to be a solution of the biharmonic equation

$$\nabla^2\nabla^2\phi = 0 \quad \ldots\ldots [3]$$

For a flanged beam with one end rigidly built-in and the other end free or loaded in shear only, when for the purpose of simplification it is assumed that the manner of load application is such that σ_x is exactly an odd function of y, the boundary conditions of

$$x = 0 \quad u = 0 \quad v = 0 \ldots\ldots\ldots\ldots [4a, b]^3$$

$$x = l \quad \sigma_x = 0 \quad \tau = \tau_0(y) \ldots\ldots\ldots\ldots [5a, b]$$

$$y = \pm h \quad A_f \frac{\partial \sigma_f}{\partial x} = \pm t\tau(x, \pm h) \quad \epsilon_f = \epsilon_x(x, \pm h) \ldots [6a]$$

$$y = \pm h \quad \sigma_y = \mp {}^1/_2 p(x) \ldots\ldots\ldots\ldots [6b]$$

Equations [4] and [5] are self-explanatory. Equation [6a] expresses the fact that the variation of the flange normal stress is

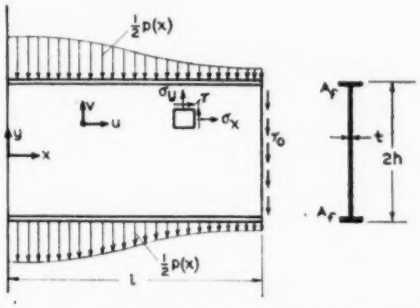

FIG. 1 FLANGED BEAM WITH ONE END RIGIDLY BUILT-IN, SHOWING LOAD APPLICATION

due to the shear acting between flange and web, and that flange and web normal strains coincide along the junction of the two structural members.[4] The particular type of load application, which is indicated by Equation [6b] and Fig. 1, has been chosen for the purpose of obtaining antisymmetry of the σ_x stresses about the axis of the beam, thus simplifying the analysis.

In order to obtain an approximate solution to this problem we write

$$\phi = F_e + F \ldots\ldots\ldots\ldots [7]$$

where F_e denotes the stress function corresponding to the elementary beam theory (which in general satisfies neither the differential Equation [3] nor all the boundary conditions). The function F determines the deviations from the elementary theory.

F_e can be written in the form

$$F_e = \frac{M(x)h^2}{I}\left[\frac{1}{6}\left(\frac{y}{h}\right)^3 - \left(m + \frac{1}{2}\right)\left(\frac{y}{h}\right)\right] = \frac{M(x)h^2}{I} g_e(y) = f_e(x)g_e(y) \ldots [8]$$

where $M(x)$ denotes the moment of the edge loads $tp(x)$ and $t\tau_0(y)$ at any section x = const, and

$$I = \frac{2}{3}h^3t(1 + 3m) \quad m = \frac{A_f}{th} \ldots\ldots\ldots\ldots [9]$$

are the moment of inertia and a form factor of the cross section. The function, Equation [8], satisfies the flange boundary conditions, Equations [5a] and [6], as well as Equation [5b] if the shear load at the free end is distributed in accordance with the assumptions of the elementary theory.

The correction term F is assumed in the form

$$F = \left[\frac{1 + 7m}{1 + 3m}\left(\frac{y}{h}\right) - 2\frac{1 + 5m}{1 + 3m}\left(\frac{y}{h}\right)^3 + \left(\frac{y}{h}\right)^5\right] h^2 f(x) = g(y)f(x) \ldots [10]$$

where $f(x)$ is a function yet to be determined. Term F has been chosen such that ϕ, as given in Equation [7], satisfies the flange-boundary conditions Equation [6]. Equations [5] for the free end are satisfied exactly by imposing appropriate boundary conditions on $f(x)$, while the remaining conditions, Equation [4] and the differential Equation [3], are satisfied approximately by minimizing the internal work of the beam, this procedure leading to a total differential equation and to additional boundary conditions for $f(x)$.

Expressions for the stresses follow from Equations [1, 7, 8, 10] in the form

$$\sigma_x = \left(\frac{y}{h}\right)\frac{M(x)h}{I} + \left[-12\frac{1 + 5m}{1 + 3m}\left(\frac{y}{h}\right) + 20\left(\frac{y}{h}\right)^3\right] f(x) \ldots [11]$$

$$\tau = -\left[\frac{1}{2}\left(\frac{y}{h}\right)^2 - \left(m + \frac{1}{2}\right)\right]\frac{M'(x)h^2}{I} - \left[\frac{1 + 7m}{1 + 3m} - 6\frac{1 + 5m}{1 + 3m}\left(\frac{y}{h}\right)^2 + 5\left(\frac{y}{h}\right)^4\right] hf'(x) \ldots [12]$$

$$\sigma_y = \left[\frac{1}{6}\left(\frac{y}{h}\right)^3 - \left(m + \frac{1}{2}\right)\left(\frac{y}{h}\right)\right]\frac{M''(x)h^3}{I} + \left[\frac{1 + 7m}{1 + 3m}\left(\frac{y}{h}\right) - 2\frac{1 + 5m}{1 + 3m}\left(\frac{y}{h}\right)^3 + \left(\frac{y}{h}\right)^5\right] h^2 f''(x) \ldots [13]$$

while for the curvature of the center line of the beam there is obtained

$$K = \left(\frac{\partial^2 v}{\partial x^2}\right)_{y=0} = \left[\frac{1}{G}\frac{\partial \tau}{\partial x} - \frac{1}{E}\left(\frac{\partial \sigma_x}{\partial y} - \nu\frac{\partial \sigma_y}{\partial y}\right)\right]_{y=0}$$

$$K = -\frac{1}{E}\left\{\frac{M(x)}{I} - 12\frac{1 + 5m}{1 + 3m}\frac{f(x)}{h^3} - (2 + \nu)\left[\frac{M''(x)h^2}{I}\left(m + \frac{1}{2}\right) - \frac{1 + 7m}{1 + 3m}\frac{f''(x)}{h}\right]\right\}$$

APPLICATION OF PRINCIPLE OF LEAST WORK

The function $f(x)$, occurring in Equations [11] to [13] for the stresses, will be determined by the method of least work, which in the present problem amounts to minimizing the internal energy W_i of the beam, given in terms of the stresses, by a suitable choice of $f(x)$.

Term W_i has the form

$$W_i = \frac{t}{2E}\int_0^l\int_{-h}^{h}\{\sigma_x^2 + \sigma_y^2 - 2\nu\sigma_x\sigma_y + 2(1 + \nu)\tau^2\}\, dydx + \frac{A_f}{E}\int_0^l \sigma_f^2 dx \ldots [14]$$

where the first integral represents the energy stored in the web,

---

[3] It should be noted that the conditions, Equations [4], of vanishing displacements at the built-in end are in practice never quite realizable due to flexibility of the support. The solution obtained without regard to this flexibility will therefore represent only an approximation in actual cases. An investigation of the limiting case seems, however, to be of interest in order to obtain an indication of trends.

[4] In order to avoid difficulties originating from the fact that, for a flanged beam, continuity of the strains at the transition from web to flange is not equivalent to continuity of the σ_x stresses when $\nu \neq 0$, it will be assumed that, in the formulas for the flanged beam, the applied load is either concentrated at the free end or uniformly distributed along the beam. Since in this case $\sigma_y(x, \pm h) = 0$ or c, it follows that $\frac{\partial \sigma_f}{\partial x} = \frac{\partial \sigma_x(x, h)}{\partial x}$. Also, in order to simplify the calculations, it is assumed that the flange area is concentrated along a line, which presupposes that the flange height is small compared with the height of the beam.

and the second integral the energy stored in the two flanges.[5]

The condition for a minimum value of W_i is, according to the rules of the calculus of variations, that the variation of W_i, δW_i vanish. Introducing Equations [1] into [14], δW_i takes the form

$$\delta W_i = \frac{t}{E}\int_0^l\int_{-h}^{h}\{\phi_{yy}\delta\phi_{yy} + \phi_{xx}\delta\phi_{xx} - \nu\phi_{xx}\delta\phi_{yy} - \nu\phi_{yy}\delta\phi_{xx} + 2(1+\nu)\phi_{xy}\delta\phi_{xy}\}\,dydx + \frac{2A_f}{E}\int_0^l [\sigma_f\delta\sigma_f]dx \quad [15]$$

By repeated integration by parts this is transformed into

$$\delta W_i = \frac{t}{E}\left\{\int_0^l\int_{-h}^{h}[\nabla^2\nabla^2\phi]\,\delta\phi dydx - \int_{-h}^{h}\left\{[\phi_{xxx} + (2+\nu)\phi_{xyy}]\delta\phi - [\phi_{xx} - \nu\phi_{yy}]\delta\phi_x\right\}_0^l dy - \int_0^l\left\{[\phi_{yyy} + (2+\nu)\phi_{yxx}]\delta\phi - [\phi_{yy} - \nu\phi_{xx}]\delta\phi_y\right\}_{-h}^{h} dx + 2(1+\nu)\left\{\left[\phi_{xy}\delta\phi\right]_0^l\right\}_{-h}^{h} + \frac{2A_f}{t}\int_0^l\sigma_f\delta\sigma_f dx\right\} = 0 \quad [16]$$

In view of the fact that the varied stresses must satisfy the same boundary conditions as the stresses themselves, it follows from [5*a*, *b*] and from [6*a*, *b*] that

$$x = l \qquad \delta\phi = 0 \qquad \delta\phi_x = 0 \quad [17a]$$

$$y = \pm h \qquad \delta\phi = 0 \qquad \pm\frac{A_f}{t}\delta\sigma_f + \delta\phi_y = 0 \quad [17b]$$

Thus all of the single integrals in Equation [16] are identically zero, with the exception of those which are taken along $x = 0$, where the displacements are prescribed,[6] and Equation [16] reduces to

$$\int_0^l\int_{-h}^{h}[\nabla^2\nabla^2\phi]\,\delta\phi dydx - \left\{\int_{-h}^{h}[(\phi_{xx} - \nu\phi_{yy})\delta\phi_x - (\phi_{xxx} + (2+\nu)\phi_{xyy})\delta\phi]dy\right\}_{x=0} = 0 \quad [17c]$$

Because of the arbitrariness of the variations occurring in Equation [17*c*], it is seen that the double integral and the two single integrals must vanish independently. Vanishing of the double integral leads to a differential equation for the function $f(x)$, and vanishing of the two single integrals results in conditions replacing the conditions of vanishing displacements at the built-in end of the beam. The results of this procedure, in addition to Equations [17*b*], constitute a fourth-order differential equation and four boundary conditions determining $f(x)$, as will now be shown.

Writing, in accordance with Equations [7, 8, 10]

$$\phi = g_s(y)f_s(x) + g(y)f(x) \quad [18]$$

then

$$\nabla^2\nabla^2\phi = g_s f_s^{IV} + 2g_s''f_s'' + gf^{IV} + 2g''f'' + g^{IV}f \quad [19]$$

$$\delta\phi = g\delta f \quad [20]$$

$$\phi_{xx} = g_s f_s'' + gf'' \qquad \phi_{yy} = g_s''f_s + g''f \quad [21]$$

$$\phi_{xxx} = g_s f_s''' + gf''' \qquad \phi_{xyy} = g_s''f_s' + g''f' \quad [22]$$

$$(\delta\phi_x)_{x=0} = g\delta f'(0) \qquad (\delta\phi)_{x=0} = g\delta f(0) \quad [23]$$

The least-work conditions, Equation [17*c*], then reduce to

$$\int_{-h}^{h}[g_s f_s^{IV} + 2g_s''f_s'' + gf^{IV} + 2g''f'' + g^{IV}f]\,gdy = 0 \quad [24]$$

$$\int_{-h}^{h}[g_s f_s''(0) + gf''(0) - \nu(g_s''f_s(0) + g''f(0))]\,gdy = 0 \quad [25]$$

$$\int_{-h}^{h}[g_s f_s'''(0) + gf'''(0) + (2+\nu)(g_s''f_s'(0) + g''f'(0))]\,gdy = 0 \quad [26]$$

The conditions, Equations [17*a*], are satisfied by prescribing

$$f(l) = 0 \qquad f'(l) = 0 \quad [27]$$

Equations [24, 25, 26] may be written in the form

$$a_4h^4\frac{d^4f}{dx^4} + 2a_2h^2\frac{d^2f}{dx^2} + a_0f = -b_4h^2\frac{d^4f_s}{dx^4} - 2b_2\frac{d^2f_s}{dx^2} \quad [28]$$

$$a_4h^2f''(0) - \nu a_2f(0) = -b_4f_s''(0) + \frac{\nu b_2}{h^2}f_s(0) \quad [29]$$

$$a_4h^3f'''(0) + (2+\nu)a_2hf'(0) = -b_4hf_s'''(0) - (2+\nu)\frac{b_2}{h}f_s'(0) \quad [30]$$

where the constants a_n and b_n are given by

$$a_4 = \frac{1}{h^5}\int_{-h}^{h}g^2dy = \frac{1}{(1+3m)^2}\left\{\frac{256}{3465} + \frac{4352}{3465}m + \frac{1280}{231}m^2\right\} \quad [31a]$$

$$a_2 = \frac{1}{h^3}\int_{-h}^{h}g''gdy = \frac{-1}{(1+3m)^2}\left\{\frac{256}{315} + \frac{256}{21}m + \frac{384}{7}m^2\right\} \quad [31b]$$

$$a_0 = \frac{1}{h}\int_{-h}^{h}g^{IV}gdy = \frac{1}{1+3m}\left\{\frac{128}{7} + \frac{1280}{7}m\right\} \quad [31c]$$

$$b_4 = \frac{1}{h^3}\int_{-h}^{h}g_sgdy = \frac{-1}{1+3m}\left\{\frac{64}{945} + \frac{256}{315}m + \frac{32}{21}m^2\right\} \quad [31d]$$

$$b_2 = \frac{1}{h}\int_{-h}^{h}g_s''gdy = \frac{1}{1+3m}\left\{\frac{16}{105} + \frac{32}{21}m\right\} \quad [31e]$$

Table 1 contains the numerical values of these constants for various values of the form factor m.

[5] To account for flexibility of the support it would be necessary to add a term for the work done in deforming the supporting structure.

[6] If, instead of prescribing the stresses at the free end ($x = l$) of the beam, conditions involving the displacements were prescribed, for instance v = constant instead of $\tau = \tau_0$, there would remain a single integral along $x = l$ leading to a further condition for $f(x)$ which would take the place of that following from $\tau(l, y) = \tau_0$. It is in this sense that the present least-work procedure is more flexible than a procedure utilizing an assumed function $f(x)$ with parameters to be determined from the minimum condition. In that case there would be no possibility of distinguishing between the two alternatives.

It may be added that Equation [16] is also suitable for a determination of the stresses in a beam, the middle section of which is at $x = 0$, with loading and support symmetrical about $x = 0$. In that case the condition, Equation [4b], of vanishing transverse displacement must be replaced by the symmetry condition of vanishing shear. This entails replacing part of the single integral in Equation [17*c*], by the condition $\delta\phi_x(0, y) = 0$ which is satisfied when $f'(0) = 0$. In that way it would be possible to obtain an approximate solution for a problem for which an exact Fourier integral solution has been given previously (7, 8).

TABLE 1 VALUES OF a_n AND b_n

m	a_4	a_2	a_0	b_4	b_2

TABLE 2 VALUES OF $k = k_r + ik_i$

m	k_r	k_i
0	3.65591	1.53813
0.1	3.44840	1.32923
1	3.21699	0.68722
∞	3.15040	0.15784

In the foregoing developments the differential Equation [28] takes the place of the biharmonic equation for the stress function in an exact analysis. Equation [29] takes the place of the condition that, at the built-in end, the transverse displacement v vanishes and Equation [30] stands for the condition that the spanwise displacement u vanishes at that end. Equations [27] require that the approximate solution satisfy exactly the condition of vanishing σ_x and parabolic or vanishing τ at the free end.

Explicit Solution of Problem for Concentrated End Load and Uniformly Distributed Load

Restricting further discussion to the case of a concentrated end load $P = t\int_{-h}^{h}\tau_0 dy$ and a uniformly distributed load P_0, and setting

$$\frac{Plh}{I} = \sigma_0 \qquad \frac{P_0hl^2}{2I} = \sigma_1 \ldots\ldots\ldots\ldots [32]$$

it follows that

$$\left.\begin{aligned} M(x) &= \frac{I}{x}\left\{\sigma_0\left(1-\frac{x}{l}\right)+\sigma_1\left(1-\frac{x}{l}\right)^2\right\} \\ M''(x) &= \frac{2I}{hl^2}\sigma_1 \qquad M^{IV}(x) = 0 \end{aligned}\right\} \ldots\ldots [33]$$

and the differential Equation [28] as well as the boundary conditions Equations [27, 29, 30] for $f(x)$, in view of Equation [8], take the form

$$a_4h^4f^{IV}(x) + 2a_2h^2f''(x) + a_0f(x) = -4b_2\sigma_1\left(\frac{h}{l}\right)^2 \ldots [34]$$

$$a_4h^2f''(0) - \nu a_2 f(0) = -2b_4\left(\frac{h}{l}\right)^2\sigma_1 + \nu b_2(\sigma_0+\sigma_1) \ldots [35]$$

$$a_4h^3f'''(0) + (2+\nu)a_2hf'(0) = (2+\nu)b_2(\sigma_0+2\sigma_1)\left(\frac{h}{l}\right) \ldots [36]$$

$$f(l) = 0 \qquad f'(l) = 0 \ldots\ldots\ldots\ldots [37]$$

The solution of Equation [34] can be written

$$f = -4\frac{b_2}{a_0}\left(\frac{h}{l}\right)^2\sigma_1 + C_1e^{k\frac{x}{h}} + \bar{C}_1e^{\bar{k}\frac{x}{h}} + C_2e^{-k\frac{x}{h}} + \bar{C}_2e^{-\bar{k}\frac{x}{h}} \ldots [38]$$

where

$$2C_1 = A_1 + iB_1 \qquad 2C_2 = A_2 + iB_2 \ldots\ldots [39]$$

are complex constants of integration, bars indicating the conjugate complex, and

$$k = k_r + ik_i = \sqrt[4]{\frac{a_0}{a_4}}\left\{\cos\left[\frac{1}{2}\tan^{-1}\left(\frac{-1}{a_2}\sqrt{a_0a_4-a_2^2}\right)\right] + i\sin\left[\frac{1}{2}\tan^{-1}\left(\frac{-1}{a_2}\sqrt{a_0a_4-a_2^2}\right)\right]\right\} \ldots [40]$$

satisfies the characteristic equation

$$a_4k^4 + 2a_2k^2 + a_0 = 0 \ldots\ldots\ldots\ldots [41]$$

of the differential Equation [34].

While for the determination of the constants of integration it is convenient to take the solution in the complex form Equation [38], for the purpose of evaluation it is better to write it in terms of real variables

$$f = -4\frac{b_2}{a_0}\left(\frac{h}{l}\right)^2\sigma_1 + e^{k_r\frac{x}{h}}\left\{A_1\cos k_i\frac{x}{h} - B_1\sin k_i\frac{x}{h}\right\} + e^{-k_r\frac{x}{h}}\left\{A_2\cos k_i\frac{x}{h} + B_2\sin k_i\frac{x}{h}\right\} \ldots [38a]$$

To simplify the discussion, it shall now be assumed that the span length l is sufficiently large in comparison with the height $2h$, so that

$$e^{-k_r\frac{l}{h}} \ll 1, \text{ say } < 0.05 \ldots\ldots\ldots\ldots [42]$$

Under this condition, which is fulfilled when

$$\frac{h}{l} < \frac{k_r}{\ln 20} \approx 1 \ldots\ldots\ldots\ldots [43]$$

it is permissible to treat the effects at the built-in end ($x = 0$) and at the free end ($x = l$) separately.

As will be seen, there is no free-end correction necessary for the beam with free-end load only, whereas, correction terms do occur at the free end for the case of a uniformly distributed load p_0. This is in accordance with the known fact that the polynomial solutions for Airy's stress function which correspond to the case of the uniformly distributed load do not fulfill the conditions of vanishing stress at the free end (9). Since this effect however occurs at a section where the stresses are very small, a quantitative discussion of the required correction has not been undertaken here.

As can also be seen, in addition to the correction terms decreasing from the edges, there occurs a uniform correction term in f which is proportional to σ_1. (It is of some interest to notice that the magnitude of this correction depends only upon σ_1 and the ratio h/l and not on m and ν, the quantity b_2/a_0, from Equations [31c, e], having the constant value $\frac{1}{120}$.) In accordance with previous knowledge, this indicates that, for the uniformly distributed load, the linear bending-stress distribution is in any case only an approximation, whatever the conditions of support of the beam.

Taking

$$f = -\frac{1}{30}\left(\frac{h}{l}\right)^2\sigma_1 + Ce^{-k\frac{x}{h}} + \bar{C}e^{-\bar{k}\frac{x}{h}} \ldots\ldots [44]$$

and disregarding the conditions at the free end, there follow from Equations [35] and [36] two conditions determining C

$$(a_4k^2 - \nu a_2)C + (a_4\bar{k}^2 - \nu a_2)\bar{C} = \nu b_2(\sigma_0+\sigma_1) - \left(\frac{h}{l}\right)^2\left(2b_4 + 4\nu\frac{a_2b_2}{a_0}\right)\sigma_1 \ldots\ldots [45]$$

$$[a_4k^3 + (2+\nu)a_2k]C + [a_4\bar{k}^3 + (2+\nu)\bar{k}]\bar{C} = -(2+\nu)\left(\frac{h}{l}\right)b_2(\sigma_0+2\sigma_1) \ldots\ldots [46]$$

These equations give

$$C = \frac{1}{\Delta}\left\{\sigma_0\left[\nu b_2(a_4\bar{k}^2 + (2+\nu)a_2\bar{k}) + (2+\nu)\left(\frac{h}{l}\right)b_2(a_4\bar{k}^2 - \nu a_2)\right] + \sigma_1\left[\left\{\nu b_2 - \left(\frac{h}{l}\right)^2\left(2b_4 + 4\nu\frac{a_2b_2}{a_0}\right)\right\}\left\{a_4\bar{k}^2 + (2+\nu)a_2\bar{k}\right\} + 2(2+\nu)\left(\frac{h}{l}\right)b_2(a_4\bar{k}^2 - \nu a_2)\right]\right\} \quad [47]$$

where

$$\Delta = -2ik_i\{a_4(a_0 - 2a_2|k|^2) - \nu a_2[(2+\nu)a_2 + (k^2 + \bar{k}^2 + 2|k|^2)a_4]\} \quad [48]$$

It is convenient for the numerical evaluation of the preceding results to separate again the cases of concentrated end load and of uniformly distributed load.

Results for Beam With Concentrated End Load

Setting

$$\sigma_1 = 0$$

one has for the constant C occurring in $f(x)$, when in Equation [47] the real and imaginary parts are separated

$$C = \frac{1}{2}(A + iB) = \frac{b_2}{\Delta}\sigma_0\left\{(2+\nu)\left[a_4(k_r^2 - k_i^2) - \nu a_2\right]\frac{h}{l} - \nu k_r\left(\sqrt{a_0a_4} - \nu a_2\right)\right\} - i\frac{b_2k_i}{\Delta}\sigma_0\left\{2(2+\nu)a_4k_r\frac{h}{l} + \nu\left(\sqrt{a_0a_4} + \nu a_2\right)\right\} \quad [49]$$

The functions $f(x)$ and $f'(x)$ which, according to Equations [11] and [12], determine the distribution of σ_x and τ are given by

$$f(x) = e^{-k_r\frac{x}{h}}\left\{A\cos k_i\frac{x}{h} + B\sin k_i\frac{x}{h}\right\} \quad [50]$$

$$hf'(x) = e^{-k_r\frac{x}{h}}\left\{(-k_rA + k_iB)\cos k_i\frac{x}{h} + (-k_iA - k_rB)\sin k_i\frac{x}{h}\right\} \quad [51]$$

TABLE 3 VALUES OF CONSTANTS OF INTEGRATION IN $f(x)$

m	ν	A/σ_0	B/σ_0
0	0	$0.0508\left(\frac{h}{l}\right)$	$0.0497\left(\frac{h}{l}\right)$

1	1/3	$0.0374\left(\frac{h}{l}\right) + 0.0063$	$0.1115\left(\frac{h}{l}\right) - 0.0549$
∞	0	$0.0351\left(\frac{h}{l}\right)$	$0.3496\left(\frac{h}{l}\right)$
∞	1/3	$0.0346\left(\frac{h}{l}\right) + 0.0052$	$0.4589\left(\frac{h}{l}\right) - 0.2073$

Table 3 contains values of A and B for various values of the form factor m and for the two values of Poisson's ratio $\nu = 0$ and $\nu = 1/3$.

Introducing these values for A and B into Equations [50] and [51], which equations in turn are introduced into Equations [11] and [12], there result explicit expressions for τ and σ_x.

In particular, shear and normal stress at the built-in end of the beam have the form

$$\tau(0,y) = \sigma_0\frac{h}{l}\left\{\left[\frac{1}{2}\left(\frac{y}{h}\right)^2 - \left(m + \frac{1}{2}\right)\right] + \frac{l}{h}\left(k_r\frac{A}{\sigma_0} - k_i\frac{B}{\sigma_0}\right)\left[\frac{1+7m}{1+3m} - 6\frac{1+5m}{1+3m}\left(\frac{y}{h}\right)^2 + 5\left(\frac{y}{h}\right)^4\right]\right\} \quad [52]$$

$$\sigma_x(0,y) = \sigma_0\left\{\frac{y}{h} + \frac{A}{\sigma_0}\left[-12\frac{1+5m}{1+3m}\frac{y}{h} + 20\left(\frac{y}{h}\right)^3\right]\right\} \quad [53]$$

and the normal stress in the extreme fiber of the beam is given by

$$\sigma_x(x,h) = \sigma_0\left\{\left(1 - \frac{x}{l}\right) + \frac{8}{1+3m}\frac{f(x)}{\sigma_0}\right\} \quad [54]$$

To obtain a picture of the situation, these stresses have been calculated for a beam having equal height and length ($h/l = 0.5$).

Figs. 2(a, b, c, d) contain the normal stress distribution at the built-in end section ($x = 0$). It is seen that the maximum stress at the flange is higher than the one given by the elementary theory. Specifically, the magnitude of the stress correction increases with decreasing flange area–web area ratio m. It is noted that Poisson's ratio ν is of appreciable influence, the stress concentration being greater for $\nu = \frac{1}{3}$ than for $\nu = 0$. For the sake of comparison there is also given the result obtained by R. Sonntag (5) for the case $m = \nu = 0$, which is seen to give a correction for the maximum stress of about 89 per cent of the correction obtained here for the corresponding case.

Figs. 3(a, b, c) contain the shear-stress distribution over the built-in end of the beam. It is seen that this distribution deviates even more from the "elementary" distribution than the corresponding normal stresses and that the influence of Poisson's ratio ν is very pronounced. The point of maximum shear is no longer at the neutral axis but is moved toward the extreme

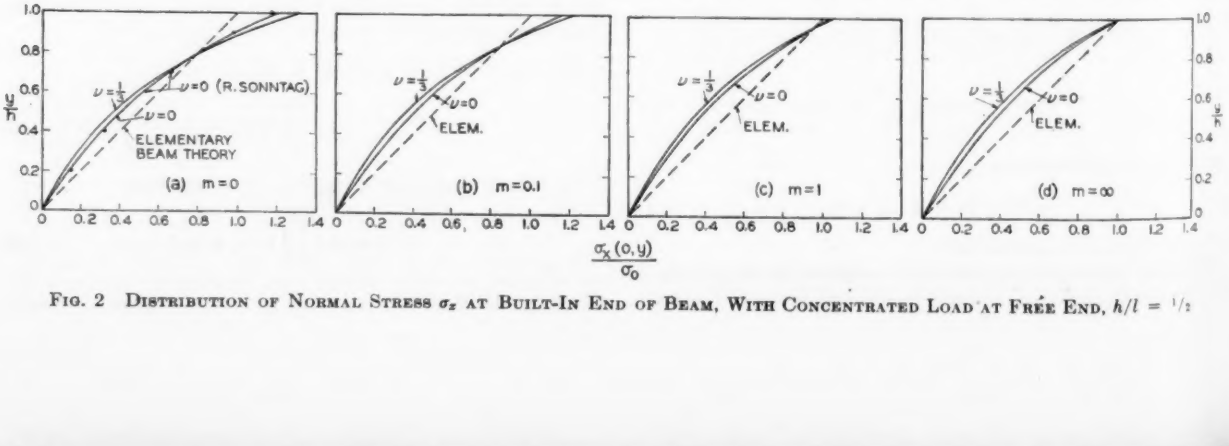

FIG. 2 DISTRIBUTION OF NORMAL STRESS σ_x AT BUILT-IN END OF BEAM, WITH CONCENTRATED LOAD AT FREE END, $h/l = 1/2$

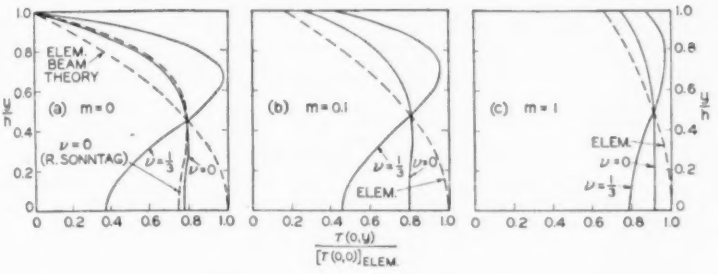

FIG. 3 DISTRIBUTION OF SHEAR STRESS τ AT BUILT-IN END OF BEAM, WITH CONCENTRATED LOAD AT FREE END, $h/l = 1/2$

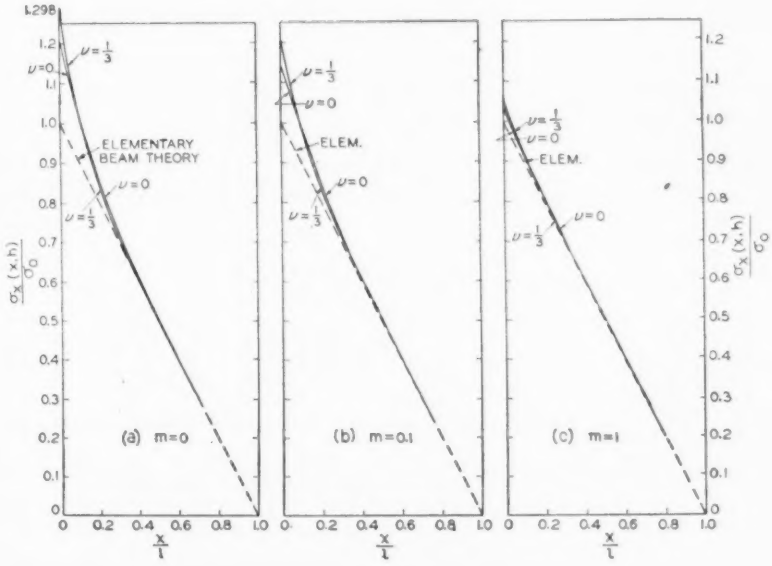

FIG. 4 SPANWISE DISTRIBUTION OF NORMAL STRESS σ_x IN THE EXTREME FIBER OF BEAM, WITH CONCENTRATED LOAD AT FREE END, $h/l = 1/2$

fibers, the further up the greater m. The value of the maximum shear is about the same for $\nu = 1/3$ as that given by the elementary theory, while for $\nu = 0$ it is considerably less.

Figs. 4(a, b, c) give the spanwise distribution of edge normal stress for various values of m and ν. They show that the deviation of the stresses from the stresses of the elementary theory does not extend effectively beyond a distance from the end section of about one half the height of the beam. They also show that the slight oscillation of the stresses about those of the elementary theory is too small to appear in the diagrams.

In Fig. 5, finally, values are plotted of what may be called a stress-concentration factor $\sigma_x(0, h)/\sigma_0$ for various values of m, ν, and h/l. Since the analytical expressions for this factor are fairly simple they are also reproduced in Table 4.

TABLE 4 VALUES OF RATIO OF MAXIMUM FIBER STRESS AND MAXIMUM ELEMENTARY FIBER STRESS, $\sigma_x(0, h)/\sigma_0$

m \ ν	0	1/3
0	$1 + 0.4065\,\frac{h}{l}$	$1.0954 + 0.4047\,\frac{h}{l}$
0.1	$1 + 0.2849\,\frac{h}{l}$	$1.0603 + 0.2830\,\frac{h}{l}$
1	$1 + 0.0759\,\frac{h}{l}$	$1.0125 + 0.0749\,\frac{h}{l}$
∞	1	1

Fig. 5 shows that the stress concentration increases with increasing height-length ratio h/l, and with increasing values of Poisson's ratio ν, and decreases with increasing form factor $m = A_f/th$. It is noteworthy that for $\nu \neq 0$ there is an increase of maximum stress even for $h/l = 0$. The explanation for this appears to be not the restraint against warping but the condition that the elements of the end section are also not permitted to move in a direction perpendicular to the beam axis.

It might finally be said that all these curves give the corrections to the elementary results which are compatible with the assumption of a third-degree polynomial for the σ_x stresses, with which it is not possible to satisfy exactly the condition of rigid clamping. Therefore it can only be said that the "average" warping has been reduced (presumably to a small fraction of the amount of warping which goes with the linear normal stress distribution). On the other hand, it is possible that the exact solution for rigid clamping may, for the beam with no flanges, lead to infinite stresses at the corners of the end section.[7] It appears not unreasonable to assume that in this case yielding, at

[7] It has, however, been established in reference (6) that no such singularity occurs if a material is assumed with no resistance to transverse (σ_y) stresses.

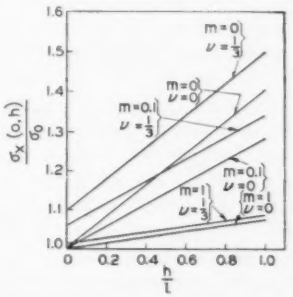

FIG. 5 VALUES OF RATIO OF MAXIMUM FIBER STRESS $\sigma_x(0, h)$, AND MAXIMUM FIBER STRESS OF ELEMENTARY THEORY σ_0, FOR VARIOUS VALUES OF FORM FACTOR $m = A_f/ht$, POISSON'S RATIO ν AND HEIGHT-SPAN RATIO $2h/l$ FOR BEAM WITH CONCENTRATED LOAD AT FREE END

1	1/3	$0.0560\left(\frac{h}{l}\right)^2 + 0.0749\left(\frac{h}{l}\right) + 0.0063$	$-0.4912\left(\frac{h}{l}\right)^2 + 0.2230\left(\frac{h}{l}\right) - 0.0549$
$\to\infty$	—	$\to m\left(\frac{h}{l}\right)^2 \times$ const	$\to m\left(\frac{h}{l}\right)^2 \times$ const

the corners of the supporting medium as well as of the beam, will lead to a redistribution of stress which then can be represented by a third-degree polynomial. In this sense, it is necessary to use the results for the case of no flanges ($m = 0$) with a certain amount of caution.

Results for Beam With Uniformly Distributed Load

Setting

$$\sigma_0 = 0$$

in Equation [47], there follows for the constant of integration, after separating into real and imaginary parts

$$C = \frac{1}{2}(A + iB)$$

$$= \sigma_1 \frac{b_2}{\Delta}\left\{2k_r\left(\frac{b_4}{b_2} + 2\nu\frac{a_2}{a_0}\right)\left(\sqrt{a_0 a_4} - \nu a_2\right)\left(\frac{h}{l}\right)^2 + 2(2+\nu)\left[a_4(k_r^2 - k_i^2) - \nu a_2\right]\left(\frac{h}{l}\right) - \nu k_r\left[\sqrt{a_0 a_4} - \nu a_2\right]\right\}$$

$$+ i\sigma_1 \frac{b_2}{\Delta} k_i\left\{2\left(\frac{b_4}{b_2} + 2\nu\frac{a_2}{a_0}\right)\left(\sqrt{a_0 a_4} + \nu a_2\right)\left(\frac{h}{l}\right)^2 - 4a_4 k_r(2+\nu)\left(\frac{h}{l}\right) - \nu\left(\sqrt{a_0 a_4} + \nu a_2\right)\right\} \quad [55]$$

Table 5 contains the values of A and B for various values of m and ν, as functions of (h/l).

According to Equation [44] the function $f(x)$ is

$$f(x) = -\frac{1}{30}\left(\frac{h}{l}\right)^2 \sigma_1 + e^{-k_r\frac{x}{h}}\left(A\cos k_i\frac{x}{h} + B\sin k_i\frac{x}{h}\right) \quad [56]$$

As before, for the shear stress and normal stress at the built-in end, taking into consideration Equations [11, 12, 33], we obtain

$$\tau(0, y) = 2\sigma_1\frac{h}{l}\left[\frac{1}{2}\left(\frac{y}{h}\right)^2 - \left(m + \frac{1}{2}\right)\right] + \sigma_1\left(k_r\frac{A}{\sigma_1} - k_i\frac{B}{\sigma_1}\right)\left[\frac{1+7m}{1+3m} - 6\frac{1+5m}{1+3m}\left(\frac{y}{h}\right)^2 + 5\left(\frac{y}{h}\right)^4\right] \quad [57]$$

$$\sigma_x(0, y) = \sigma_1\frac{y}{h} + \sigma_1\left[-12\frac{1+5m}{1+3m}\frac{y}{h} + 20\left(\frac{y}{h}\right)^3\right]\left[\frac{A}{\sigma_1} - \frac{1}{30}\left(\frac{h}{l}\right)^2\right] \quad [58]$$

For the normal stress in the extreme fiber of the beam there follows

$$\sigma_x(x, h) = \sigma_1\left\{\left(1 - \frac{x}{l}\right)^2 + \frac{8}{1+3m}\frac{f(x)}{\sigma_1}\right\} \quad [59]$$

Again these stresses have been calculated for a beam having equal height and length ($h/l = 0.5$).

Figs. 6(a, b, c) contain the normal stress distribution over the end section, $x = 0$. For $m = 0$ and $m = 0.1$ there is qualitatively the same behavior as in the case of the concentrated load, i.e., the maximum stress is higher for $\nu = 1/3$ than for $\nu = 0$ and higher for $m = 0$ than for $m = 0.1$. Quantitatively, it is seen that the difference between the cases $\nu = 0$ and $\nu = 1/3$ is less noticeable than before and—most important—the difference between the maximum stress $\sigma_x(0, h)$ and the elementary extreme fiber stress σ_1 is more than twice as great as the corresponding difference for the same beam with concentrated end load. For $m = 1$ the maximum stress is again only slightly greater than the corresponding elementary stress, while in this case $\nu = 1/3$ gives a $\sigma_x(0, h)$ which is smaller than the corresponding value for $\nu = 0$.

Regarding the limiting case $m = \frac{A_f}{th} \to \infty$ it is seen that, while the end-section shear $\tau(0, y)$ behaves qualitatively as in the case

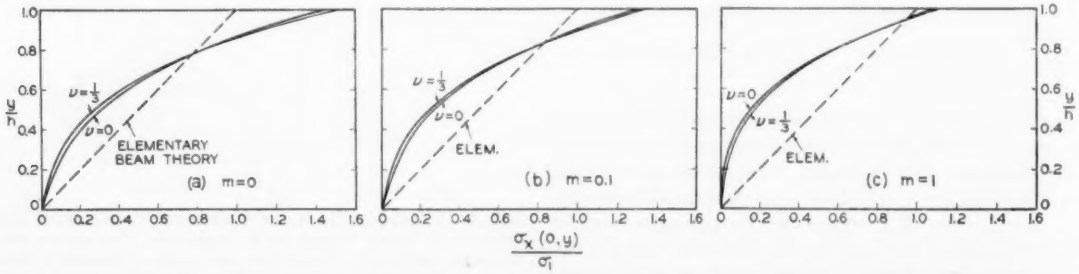

FIG. 6 DISTRIBUTION OF NORMAL STRESSES AT BUILT-IN END OF CANTILEVER BEAM, WITH UNIFORMLY DISTRIBUTED LOAD, $h/l = 1/2$

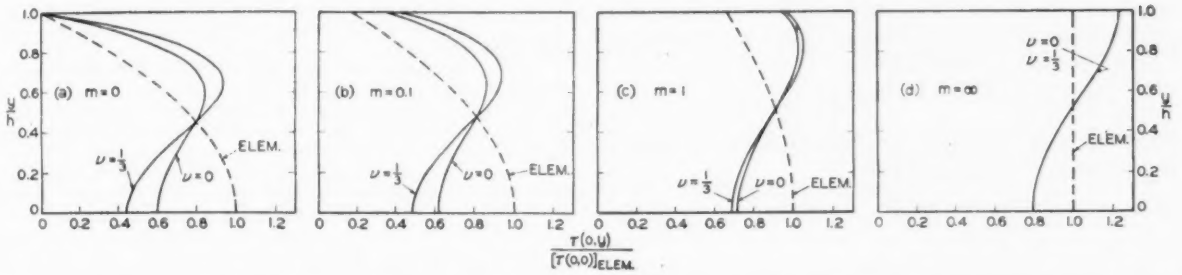

FIG. 7 DISTRIBUTION OF SHEAR STRESS τ AT BUILT-IN END OF CANTILEVER BEAM, WITH UNIFORMLY DISTRIBUTED LOAD, $h/l = 1/2$

TABLE 6 VALUES OF $\sigma_x(0, h)/\sigma_1$ FOR A BEAM WITH UNIFORMLY DISTRIBUTED LOAD

$m \backslash \nu$	0	1/3
0	$1 + 0.8130\left(\frac{h}{l}\right) + 0.1220\left(\frac{h}{l}\right)^2$	$1.0954 + 0.8095\left(\frac{h}{l}\right) + 0.0047\left(\frac{h}{l}\right)^2$
0.1	$1 + 0.5699\left(\frac{h}{l}\right) + 0.0989\left(\frac{h}{l}\right)^2$	$1.0603 + 0.5661\left(\frac{h}{l}\right) + 0.0029\left(\frac{h}{l}\right)^2$
1	$1 + 0.1518\left(\frac{h}{l}\right) + 0.1164\left(\frac{h}{l}\right)^2$	$1.0125 + 0.1498\left(\frac{h}{l}\right) + 0.0453\left(\frac{h}{l}\right)^2$

of the concentrated end load, there is a fundamental difference in the behavior of $\sigma_x(0, y)$. Equation [58] and Table 5 indicate that for $m \to \infty$ also $\sigma_x(0, y) \to \infty$ except when $y = \pm h$ where the correction again becomes finite. Tracing back the reason for the behavior it is seen that the constants A and B behave like b_4 which according to Equation [31d] increases like m itself. Since b_4, according to Equation [35], occurs in the condition taking the place of $\epsilon_y(0, y) = 0$ in an exact analysis it is seen that the existence of the transverse normal stress σ_y is responsible for what happens. It is thought, however, that this result with regard to the limiting behavior of the present solution is not necessarily the same result which would be obtained from an exact solution so that the conclusive answer to the question as to what happens when $m \to \infty$ is yet to be given.

Figs. 7(a, b, c, d) contain the distributions of shear over the built-in section. Again the point of maximum shear is moved toward the extreme fibers of the beam and the value of the maximum shear stress is greater for $\nu = 1/3$ than for $\nu = 0$. While for $m = 0$ and $m = 0.1$, the maximum elementary shear stress is greater than $[\tau(0, y)]_{max}$, the opposite is true for $m = 1$ and $m \to \infty$.

In Figs. 8(a, b, c) are given the spanwise distribution of the extreme fiber stress $\sigma_x(x, h)$ for different values of m and ν. In the neighborhood of the free end ($x = l$), $\sigma_x(x, h)$ instead of going down to zero actually reverses its sign, with the magnitude of this stress about 5 per cent of the maximum elementary fiber stress. The reason for this behavior is to be found in the fact that two of the constants of integration in $f(x)$ have been set equal to zero instead of being determined from the conditions of vanishing stress at the free end. If the more elaborate calculation had been carried through, the result would have been $\sigma_x(l, y) = 0$ as it should be.

Fig. 9 incorporates the values of the stress-concentration factor $\sigma_x(0, h)/\sigma_1$, for different values of m, ν, and h/l, which are given by the functions of Table 6.

A comparison of Tables 4 and 6 gives the noteworthy result that the ratio $[\sigma_x(0, h) - \sigma_1]/\sigma_1$ for a beam with uniformly distributed load is about twice as great as the corresponding ratio for the same beam with concentrated end load.

A generalization of this statement can be obtained if one considers the stress in a beam of length l with distributed load as the resultant of stresses due to infinitesimal concentrated loads $p(\xi)d\xi$ applied at a distance ξ from the fixed end. Each such element of loading produces a distribution of stress at the fixed end nearly equal to that which would be produced if the beam were of length ξ and a load $p(\xi)d\xi$ were acting at the free end. This argument holds for any distribution of load and its quantitative result is that the concentration of stress characterized by the value of $[\sigma_x(0, h) - \sigma(0, h)_{elem.}]/\sigma(0, h)_{elem.}$ is about the same for a beam of length l, with arbitrary loading, as for a beam of length L, with concentrated end load, L being the distance between the fixed end and the center of gravity of the load curve.

Since, according to Table 4, the ratio $[\sigma_x(0, h) - \sigma_0]/\sigma_0$ is nearly proportional to $1/l$ and since for a uniformly distributed load $L = l/2$ it follows, in particular, that

$$[\sigma_x(0, h) - \sigma_1]/\sigma_1 \approx 2[\sigma_x(0, h) - \sigma_0]/\sigma_0$$

in accordance with the formulas of Tables 4 and 6. In general, for any spanwise distribution of load

$$\left[\sigma_x(0, h) - \frac{M(0)h}{I}\right] \Big/ \frac{M(0)h}{I} \approx \frac{l}{L}\,[\sigma_x(0, h) - \sigma_0]/\sigma_0$$

where the quotient of stresses on the right-hand side is given in Table 4.

Buckling of Semimonocoque Structures Under Compression

By TSUN KUEI WANG,[1] STANFORD UNIVERSITY, CALIF.

This paper presents an investigation of the strength of a stiffened cylindrical shell under the action of uniform axial compression. It is assumed that the cylindrical structure is a very thin tube of circular cross section; its reinforcements consist essentially of a great number of uniform longitudinal stiffeners and a great number of uniform transverse rings. It is often desirable to know the critical value of the compressive load for the buckling of such a structure.

IN aeronautical construction, the sheet covering of the semimonocoque structure is so thin that it contributes very little to the structural resistance in comparison with the stiffeners and rings. Thus, in attacking the problem of the over-all or general instability of this type of structure, a portion of the sheet covering is regarded as a part of the stiffeners, and the stability of a structural grid of effective longitudinal stiffeners and transverse rings is analyzed.

Several simplifying assumptions must be made in order to render the application of analytical methods possible. (1) It is assumed that the structure under consideration has a large number of identical equally spaced longitudinal stiffeners and a great number of identical equally spaced transverse rings. (2) A stiffener with its corresponding effective width of sheet is assumed to behave as a column which is not to fail torsionally and locally. The total deflection of this stiffener during buckling is determined by its two perpendicular components, i.e., by the radial displacement w_r and the tangential displacement w_t. (3) Each of the intermediate rings, originally plane, remains plane after bending. (4) The end rings of the structure are assumed to be absolutely rigid, while the longitudinal stiffeners are hinged to them.

Notations used in this paper are shown in Fig. 1. The origin is taken at the left end of the structure and the x axes are directed along the axes of the stiffeners. The radial deflection w_r is defined as positive toward the axis of the cylinder, and the tangential deflection w_t is defined in the counterclockwise direction. The angle ϕ is measured counterclockwise from the vertical radius of the cross section. Additional notations are used, as follows:

l = total length of cylinder
R = radius of rings
p = number of intermediate rings
q = total number of stiffeners
P = compressive force per stiffener

Calculating Critical Value of Compressive Force

In calculating the critical value of the compressive force P, the energy method will be used. The method consists essentially of assuming the radial deflection w_r of the cylindrical structure in the form of a double trigonometrical series of a type which satisfies the end conditions, obtaining the tangential deflection w_t by the assumption of the inextensional deformations of rings, and determining the critical value of the compressive force P from the general energy consideration (refer to Equation [4]). It is assumed initially that each of the stiffeners is perfectly straight and compressed by the centrally applied load P. If the compressive load is less than its critical value, the stiffener remains straight. By increasing gradually the compressive load P, a condition is reached in which the straight form of equilibrium becomes unstable and a slight lateral buckling occurs. The critical load is then defined as the smallest load that can keep the stiffener in a slightly bent form.

As assumed, the end rings of the cylinder do not change shape during buckling, therefore the deflections w_r and w_t along the end rings must be zero. At the same time the ends of the stiffeners can rotate freely with respect to the circumferential axes of the end rings, i.e., there are no bending moments along these end rings. Thus, the ends of the stiffeners will be considered as simply supported. The analytical expressions of the end conditions in this case are

$$w_r = 0 \text{ and } \frac{d^2w_r}{dx^2} = 0 \text{ for } x = 0, l$$

and

$$w_t = 0 \text{ and } \frac{d^2w_t}{dx^2} = 0 \text{ for } x = 0, l$$

In general, the radial displacements w_r can be represented in the form of trigonometric series and the tangential displacements

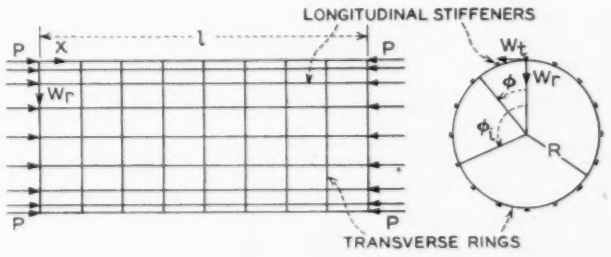

FIG. 1

w_t will be taken in such a form as to make the extension of the center line of the rings zero.[2] The final relation between w_r and w_t for this condition of inextensional deformation of the rings is

$$w_r = \frac{dw_t}{d\phi} \quad \ldots\ldots\ldots\ldots\ldots\ldots [1]$$

[1] Department of Mechanical Engineering, Stanford University.

Presented at the Annual Meeting, New York, N. Y., December 1–5, 1941, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until October 10, 1942, for publication at a later date. Discussion received after the closing date will be returned.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

[2] The discussion of inextensional deformations of rings and shells was originated by Lord Rayleigh. His investigation was based upon the fact, in the case of bending of thin rings, that the displacements due to extension of the center line of a ring are usually negligibly small in comparison with the displacements due to bending. Refer to "Theory of Sound," by John William Strutt, Baron Rayleigh, Macmillan & Company, Ltd., London, 1894–1896, chapter 2, Xa.

The deflection w_r of the structure during buckling can be represented by the following series

$$w_r = \sum_{m=1,2,3,\ldots}^{m=\infty} \sum_{n=2,3,4,\ldots}^{n=\infty} a_{mn} \cos n\phi \sin \frac{m\pi x}{l} \ldots [2]$$

where m and n indicate the numbers of half-waves and whole-waves in which the stiffeners and rings are deflected respectively during buckling.

Then the tangential displacement w_t may be obtained with the aid of Equation [1]

$$w_t = \sum_{m=1,2,3,\ldots}^{m=\infty} \sum_{n=2,3,4,\ldots}^{n=\infty} \frac{a_{mn}}{n} \sin n\phi \sin \frac{m\pi x}{l} \ldots [3]$$

Before buckling of the structure occurs, the total strain energy is stored only in the form of an axial compression. During buckling, the strain energy will increase, due partly to bending of the rings and partly to buckling of the stiffeners. At the critical value of the compressive load P, this increase in strain energy must be equal to the work done by the compressive load as the distances between the ends of the stiffeners shorten owing to buckling. Thus

$$\sum_{i=1}^{i=q} (V_{isr} + V_{ist}) + \sum_{i=1}^{i=p} V_{ir} = \sum_{i=1}^{i=q} (W_{ir} + W_{it}) \ldots [4]$$

where V_{ir} = strain energy stored in ith ring
V_{isr}, V_{ist} = strain energies stored in ith stiffener in radial and tangential directions, respectively
W_{ir}, W_{it} = works done by P during buckling of ith stiffener in radial and tangential directions, respectively.

Substituting x_i for x in Equation [2] and using the notation

$$A_{in} = a_{1n} \sin \frac{\pi x_i}{l} + a_{2n} \sin \frac{2\pi x_i}{l} + a_{3n} \sin \frac{3\pi x_i}{l} + \ldots \ldots [5]$$

the deflection curve of the ith ring is

$$w_{ir} = \sum_{n=2,3,4,\ldots}^{n=\infty} A_{in} \cos n\phi$$

The strain energy[3] of this ring can be expressed as

$$V_{ir} = \frac{EI_r}{R^3} \int_0^{\pi} \left[\left(\frac{d^2 w_{ir}}{d\phi^2} \right)^2 + 2w_{ir} \left(\frac{d^2 w_{ir}}{d\phi^2} \right) + w_{ir}^2 \right] d\phi$$

$$= \frac{EI_r \pi}{2R^3} \sum_{n=2,3,4,\ldots}^{n=\infty} (n^2 - 1)^2 A_{in}^2 \ldots [6]$$

where EI_r is the flexural rigidity of the rings.

In expressing the deflection curves for the ith stiffener, we may substitute ϕ_i for ϕ in Equations [2] and [3], respectively, and use the notations

$$\left.\begin{aligned} B_{mi} &= a_{m2} \cos 2\phi_i + a_{m3} \cos 3\phi_i + a_{m4} \cos 4\phi_i + \ldots\ldots \\ \text{and} \\ C_{mi} &= \frac{a_{m2}}{2} \sin 2\phi_i + \frac{a_{m3}}{3} \sin 3\phi_i + \frac{a_{m4}}{4} \sin 4\phi_i + \ldots \end{aligned}\right\} [7]$$

[3] "Strength of Materials," by S. Timoshenko, D. Van Nostrand Company, Inc., New York, N. Y., 1936, pp. 435 and 459.

Thus, the deflection curve for the ith stiffener in the radial direction is

$$w_{isr} = \sum_{m=1,2,3,\ldots}^{m=\infty} B_{mi} \sin \frac{m\pi x}{l}$$

and the bending energy[4] of the ith stiffener due to this deflection is

$$V_{isr} = \frac{EI_{sr}}{2} \int_0^l \left(\frac{d^2 w_{isr}}{dx^2} \right)^2 dx$$

where EI_{sr} is the flexural rigidity of the stiffeners in the radial direction.

Hence

$$V_{isr} = \frac{\pi^4 EI_{sr}}{4l^3} \sum_{m=1,2,3,\ldots}^{m=\infty} m^4 B_{mi}^2 \ldots\ldots\ldots\ldots [8]$$

The deflection curve for the ith stiffener in the tangential direction is

$$w_{ist} = \sum_{m=1,2,3,\ldots}^{m=\infty} C_{mi} \sin \frac{m\pi x}{l}$$

and the bending energy of the ith stiffener due to this deflection is

$$V_{ist} = \frac{EI_{st}}{2} \int_0^l \left(\frac{d^2 w_{ist}}{dx^2} \right)^2 dx$$

where EI_{st} is the flexural rigidity of the stiffeners in the tangential direction.

Hence

$$V_{ist} = \frac{\pi^4 EI_{st}}{4l^3} \sum_{m=1,2,3,\ldots}^{m=\infty} m^4 C_{mi}^2 \ldots\ldots\ldots\ldots [9]$$

During buckling of the cylinder, there is a longitudinal displacement or shortening between the end points of each stiffener due to the radial and tangential deflections. Owing to this displacement, the forces P produce work which can be expressed[5] for the ith stiffener as the sum of

$$W_{ir} = \frac{P}{2} \int_0^l \left(\frac{dw_{isr}}{dx} \right)^2 dx$$

$$= \frac{\pi^2 P}{4l} \sum_{m=1,2,3,\ldots}^{m=\infty} m^2 B_{mi}^2 \ldots\ldots\ldots\ldots [10]$$

and

$$W_{it} = \frac{P}{2} \int_0^l \left(\frac{dw_{ist}}{dx} \right)^2 dx$$

$$= \frac{\pi^2 P}{4l} \sum_{m=1,2,3,\ldots}^{m=\infty} m^2 C_{mi}^2 \ldots\ldots\ldots\ldots [11]$$

Substituting Equations [6] and [8] to [11] into Equation [4]

[4] "Strength of Materials," by S. Timoshenko.

[5] Ibid., p. 38; and "Theory of Elastic Stability," by S. Timoshenko, McGraw-Hill Book Company, Inc., New York, N. Y., 1936, p. 27.

and proceeding with a summation of the series as shown in the Appendix, we obtain

$$P = \frac{\pi^2 E I_{sr}}{l^2} \frac{n^2}{n^2+1}\left[\left(1+\frac{I_{st}}{n^2 I_{sr}}\right)m^2 + \frac{2I_r(p+1)l^3}{\pi^3 I_{sr} q R^3}\frac{(n^2-1)^2}{m^2}\right] \quad \ldots\ldots\ldots\ldots [12]$$

So far as n in this expression is concerned, the smallest value of the compressive load will be obtained by taking n equal to 2. The physical significance of this is that the cylindrical structure buckles in such a manner that there can be several half-waves in the longitudinal stiffeners but only 4 half-waves, or elliptical shape, in the transverse rings. Substitution of $n = 2$ in Equation [12], thus yields Equation [13], as follows:

$$P_{cr} = \frac{\pi^2 E I_{sr}}{l^2}\left\{\frac{4}{5}\left[\left(1+\frac{I_{st}}{4I_{sr}}\right)m^2 + \frac{18I_r(p+1)l^3}{\pi^3 I_{sr} q R^3}\times\frac{1}{m^2}\right]\right\} \quad \ldots\ldots\ldots\ldots [13]$$

where m can be taken equal to 1, 2, 3, ...

In Equation [13], the first factor represents the Euler load for the buckling of a bar with hinged ends and is designated by P_{eu} throughout the paper. The second factor indicates in what proportion the stability of the stiffeners reinforced by rings is greater than the stability of an isolated stiffener. The magnitude of the latter depends upon the numerical values of the ratios $\frac{I_r}{I_{sr}}, \frac{I_{st}}{I_{sr}}, \frac{l}{R}$, and $\frac{p+1}{q}$ as well as on the number m of the half-waves into which the stiffeners buckle. If, however, the geometrical dimensions of the cylinder are fixed, the number m can be uniquely determined.

Determining Number of Half Waves Into Which Stiffeners Buckle

The determination of this number m must be performed in such a way that its value should make the right-hand member of Equation [13] a minimum. This can be done graphically. Taking m equal to 1, 2, 3, ... in Equation [13] with any suitable value of I_{st}/I_{sr}, a system of straight lines for P_{cr}/P_{eu} against $2I_r(p+1)l^3/I_{sr}\pi^3 R^3 q$ is obtained. This is plotted in Fig. 2, with a value of I_{st}/I_{sr} equal to 0.5. With these lines, the critical value of the compressive load P for any given value of $2I_r(p+1)l^3$

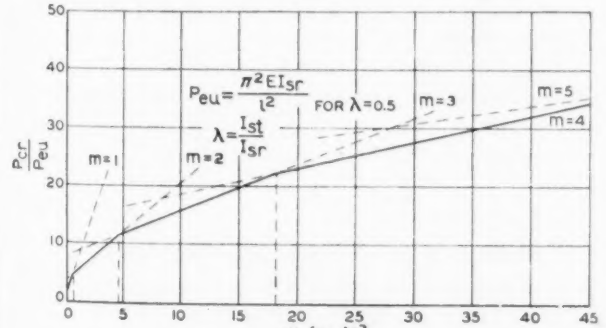

Fig. 2

$/I_{sr}\pi^3 R^3 q$ can be determined. It is only necessary to take the corresponding point on the axis of abscissas and to choose the line having the smallest ordinate for that point. We can see that for very short stiffeners, the line $m = 1$ gives the smallest ordinates. This corresponds to the buckling of the stiffeners into a single half-wave. Beginning with the point of intersection of lines $m = 1$ and $m = 2$, the second line has the smallest ordinates, i.e., the stiffeners buckle into two half waves, and this holds up to the point of intersection of lines $m = 2$, $m = 3$, etc. Since the slopes of the lines are all positive, the point of intersection of the lines $m = i$ and $m = (i + 1)$ evidently has the smallest ordinate for the segment of the line $m = (i + 1)$ between $m = i$ and $m = (i + 2)$. In Fig. 2 the portions of the lines defining the ratio of critical values of the compressive load P to the Euler load P_{eu} are shown by full lines.

Suppose the value of $2I_r(p+1)l^3/I_{sr}\pi^3 R^3 q$ has the magnitude at which the number of half-waves changes from i to $(i + 1)$. It is evident that this value corresponds to the transition point

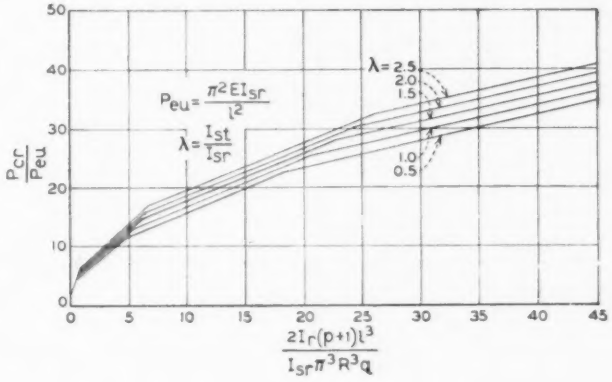

Fig. 3

from line $m = i$ to line $m = (i + 1)$ and, at this value, Equation [13] should give the same result for P_{cr} independently of whether $m = i$ or $m = (i + 1)$. By substituting the numbers i and $(i + 1)$ for m in Equation [13], respectively, and then equating these two expressions, we finally obtain

$$\left(\frac{9}{1+\frac{I_{st}}{4I_{sr}}}\right)\left(\frac{2I_r(p+1)l^3}{I_{sr}\pi^3 R^3 q}\right) = i^2(i+1)^2$$

This is the equation for calculating the transition points for curves with any suitable value of I_{st}/I_{sr}. In Fig. 2, these points are indicated by vertical dotted lines.

A family of broken lines of P_{cr}/P_{eu} against $2I_r(p+1)l^3/I_{sr}\pi^3 R^3 q$ for different values of I_{st}/I_{sr} is plotted in Fig. 3. From this figure or Equation [13], it is seen that the larger the value of I_{sr} or I_{st}, the greater will be the strength of the structure. However, the increase in strength is greater due to increase in I_{sr} than due to increase in I_{st}. This is very important for the practical application.

For larger values of m, the envelopes of the broken lines of Fig. 3 are very useful. Each of these envelopes is a curve which has the line elements of each broken line as tangents, and can be represented by the equation

$$\frac{P_{cr}}{P_{eu}} = \frac{24}{5}\left[\left(1+\frac{I_{st}}{4I_{sr}}\right)\frac{2I_r(p+1)l^3}{I_{sr}\pi^3 R^3 q}\right]^{1/2}$$

From this equation it can be seen that if all the members of these structures have the same geometrical dimensions, the critical values of the compressive load P per stiffener are proportional to the square roots of the numbers of their rings plus 1, and inversely proportional to the square roots of the numbers of their stiffeners, that is

$$P_{cr} \sim \left(\frac{p+1}{q}\right)^{1/2}$$

If the structures are considered as a whole, the total compressive load carried by each structure is qP, and the critical values of these loads are then proportional to the square roots of the products of the numbers of their rings plus 1 and stiffeners, that is

$$qP_{cr} \sim [(p+1)q]^{1/2}$$

The first statement means that, in the structure having fewer rings or more stiffeners, the buckling load per stiffener is smaller than that in the structure having more rings or fewer stiffeners; while the second statement means that the greater the number of rings or stiffeners or both, the higher is the total compressive load which the structure can carry.

Appendix

By making a substitution of Equations [6, 8, 9, 10, and 11] into Equation [4], the compressive force P at which a buckled form is possible will be

$$P = \frac{\dfrac{2EI_r}{R^3}\sum_{i=1}^{i=p}\sum_{n=2,3,4,\ldots}^{n=\infty}(n^2-1)^2A_{in}^2 + \dfrac{\pi^3EI_{sr}}{l^3}\sum_{i=1}^{i=q}\sum_{m=1,2,3,\ldots}^{m=\infty}m^4B_{mi}^2 + \dfrac{\pi^3EI_{sl}}{l^3}\sum_{i=1}^{i=q}\sum_{m=1,2,3,\ldots}^{m=\infty}m^4C_{mi}^2}{\dfrac{\pi}{l}\left(\sum_{i=1}^{i=q}\sum_{m=1,2,3,\ldots}^{m=\infty}m^2B_{mi}^2 + \sum_{i=1}^{i=q}\sum_{m=1,2,3,\ldots}^{m=\infty}m^2C_{mi}^2\right)} \quad \ldots [14]$$

To simplify the numerator and the denominator in Equation [14], the following steps will be taken:
By putting

$$\sin\frac{m\pi x_i}{l} = \sin\frac{m\pi i}{p+1} \qquad \sin n\phi_i = \sin\frac{2n\pi i}{q} \qquad \cos n\phi_i = \cos\frac{2n\pi i}{q}$$

and substituting them into Equations [5] and [7], the summation of the square of expression A_{in} from i to p and that of the squares of expressions B_{mi} and C_{mi} from i to q can be presented as follows

$$\left.\begin{aligned}
\sum_{i=1}^{i=p}A_{in}^2 &= \sum_{i=1}^{i=p}\left(a_{1n}\sin\frac{\pi i}{p+1} + a_{2n}\sin\frac{2\pi i}{p+1} + a_{3n}\sin\frac{3\pi i}{p+1} + \ldots\right)^2 \\
\sum_{i=1}^{i=q}B_{mi}^2 &= \sum_{i=1}^{i=q}\left(a_{m2}\cos\frac{4\pi i}{q} + a_{m3}\cos\frac{6\pi i}{q} + a_{m4}\cos\frac{8\pi i}{q} + \ldots\right)^2
\end{aligned}\right\} \quad [15]$$

and

$$\sum_{i=1}^{i=q}C_{mi}^2 = \sum_{i=1}^{i=q}\left(\frac{a_{m2}}{2}\sin\frac{4\pi i}{q} + \frac{a_{m3}}{3}\sin\frac{6\pi i}{q} + \frac{a_{m4}}{4}\sin\frac{8\pi i}{q} + \ldots\right)^2$$

It can be seen that Equations [15] contain the finite summations of the following type

$$\sum_{i=1}^{i=p}\sin\frac{m\pi i}{p+1}\sin\frac{n\pi i}{p+1}$$

For practical application only a few terms of the general expressions, Equations [2] and [3], need be taken with m and n as small integers, while the cylinder under consideration has a great number of longitudinal stiffeners and transverse rings so that integers p and q are relatively large. Thus, it can be assumed that either of m and n is not greater than both $\left(\frac{p+1}{2}\right)$ and $\frac{q}{2}$. Under this condition, it is concluded:[6]

1 Either $m+n$ or $m-n$ is not a multiple of $2(p+1)$, which causes

$$\sum_{i=1}^{i=p}\sin\frac{m\pi i}{p+1}\sin\frac{n\pi i}{p+1} = 0 \text{ when } m \neq n$$

2 Both $m+n$ and $m-n$ are not multiples of q, which cause

$$\sum_{i=1}^{i=q}\cos\frac{2m\pi i}{q}\cos\frac{2n\pi i}{q} = 0, \text{ when } m \neq n$$

3 Integer m is not a multiple of $p+1$, which causes

$$\sum_{i=1}^{i=p}\sin^2\frac{m\pi i}{p+1} = \frac{p+1}{2}$$

4 Integer $2n$ is not a multiple of q, which causes

$$\sum_{i=1}^{i=q}\cos^2\frac{2n\pi i}{q} = \frac{q}{2}$$

Hence, in Equations [15], those terms containing the products of the coefficients such as $a_{1n}a_{2n}$, $a_{1n}a_{3n}$, ..., $a_{m2}a_{m3}$, $a_{m2}a_{m4}$, . . . disappear and only those with squares of the coefficients remain. As a result of this fact, Equations [15] become

[6] "Elementary Treatise on Fourier Series and Spherical Harmonics," by W. E. Byerly, Ginn & Company, Boston, Mass., 1893, pp. 34–35.

$$\sum_{i=1}^{i=p} A_{in}^2 = \frac{p+1}{2}\left(a_{1n}^2 + a_{2n}^2 + a_{3n}^2 + \cdots\cdots\right) = \frac{p+1}{2}\sum_{m=1,2,3,\ldots}^{m=\infty} a_{mn}^2 \quad \ldots\ldots [16]$$

$$\sum_{i=1}^{i=q} B_{mi}^2 = \frac{q}{2}\sum_{n=2,3,4,\ldots}^{n=\infty} a_{mn}^2 \quad \ldots\ldots [17] \qquad \text{and} \qquad \sum_{i=1}^{i=q} C_{mi}^2 = \frac{q}{2}\sum_{n=2,3,4,\ldots}^{n=\infty} \frac{a_{mn}^2}{n^2} \quad \ldots\ldots [18]$$

By using the result of Equation [16], the following summation is obtained:

$$\sum_{i=1}^{i=p}\sum_{n=2,3,4,\ldots}^{n=\infty}(n^2-1)^2 A_{in}^2 = \sum_{n=2,3,4,\ldots}^{n=\infty}\left[(n^2-1)^2\sum_{i=1}^{i=p} A_{in}^2\right] = \sum_{n=2,3,4,\ldots}^{n=\infty}\left[(n^2-1)^2\frac{p+1}{2}\sum_{m=1,2,3,\ldots}^{m=\infty} a_{mn}^2\right]$$

$$= \frac{p+1}{2}\sum_{m=1,2,3,\ldots}^{m=\infty}\sum_{n=2,3,4,\ldots}^{n=\infty}(n^2-1)^2 a_{mn}^2 \ldots [19]$$

Similarly, using the results of Equations [17] and [18], we obtain

$$\sum_{i=1}^{i=q}\sum_{m=1,2,3,\ldots}^{m=\infty} m^4 B_{mi}^2 = \frac{q}{2}\sum_{m=1,2,3,\ldots}^{m=\infty}\sum_{n=2,3,4,\ldots}^{n=\infty} m^4 a_{mn}^2 \ldots [20]$$

$$\sum_{i=1}^{i=q}\sum_{m=1,2,3,\ldots}^{m=\infty} m^2 B_{mi}^2 = \frac{q}{2}\sum_{m=1,2,3,\ldots}^{m=\infty}\sum_{n=2,3,4,\ldots}^{n=\infty} m^2 a_{mn}^2 \ldots [21]$$

$$\sum_{i=1}^{i=q}\sum_{m=1,2,3,\ldots}^{m=\infty} m^4 C_{mi}^2 = \frac{q}{2}\sum_{m=1,2,3,\ldots}^{m=\infty}\sum_{n=2,3,4,\ldots}^{n=\infty} \frac{m^4}{n^2} a_{mn}^2 \ldots [22]$$

and

$$\sum_{i=1}^{i=q}\sum_{m=1,2,3,\ldots}^{m=\infty} m^2 C_{mi}^2 = \frac{q}{2}\sum_{m=1,2,3,\ldots}^{m=\infty}\sum_{n=2,3,4,\ldots}^{n=\infty} \frac{m^2}{n^2} a_{mn}^2 \ldots [23]$$

Substitution of the Equations [19, 20, 21, 22, 23] into Equation [14] yields

$$P = \frac{\dfrac{EI_r(p+1)}{R^3}\displaystyle\sum_{m=1,2,3,\ldots}^{m=\infty}\sum_{n=2,3,4,\ldots}^{n=\infty}(n^2-1)^2 a_{mn}^2 + \dfrac{\pi^2 EI_x q}{2l^3}\sum_{m=1,2,3,\ldots}^{m=\infty}\sum_{n=2,3,4,\ldots}^{n=\infty} m^4 a_{mn}^2 + \dfrac{\pi^2 EI_y q}{2l^3}\sum_{m=1,2,3,\ldots}^{m=\infty}\sum_{n=2,3,4,\ldots}^{n=\infty}\frac{m^4}{n^2} a_{mn}^2}{\dfrac{\pi q}{2l}\left[\displaystyle\sum_{m=1,2,3,\ldots}^{m=\infty}\sum_{n=2,3,4,\ldots}^{n=\infty}\left(m^2+\frac{m^2}{n^2}\right) a_{mn}^2\right]} \quad \ldots\ldots [24]$$

To find the critical value of the compressive load P, it is necessary to adjust the coefficients a_{mn} in such a manner as to make Equation [24] a minimum. This can be done on the basis of the following: Suppose we have a series of unequal fractions

$$\frac{a}{b}, \quad \frac{c}{d}, \quad \frac{e}{f} \quad \ldots\ldots [25]$$

where $a, b, c, \ldots\ldots$ are assumed positive. The fraction

$$\frac{a+c+e+\ldots\ldots}{b+d+f+\ldots\ldots} \quad \ldots\ldots [26]$$

in which the numerator is the sum of the numerators of series [25] and the denominator the sum of the denominators of series [25] is evidently of some intermediate value between the largest and the smallest of the fractions series [25]. Comparing series [25] and Equation [24], it can be concluded that the latter will be a minimum if we take only one term of the series in each numerator and denominator, that is, by making all coefficients a_{12}, a_{13}, a_{22}, $\ldots\ldots$, except one, equal to zero. If the coefficient is a_{mn}, different from zero, Equation [24] will be reduced to the form of Equation [12] as presented.

ACKNOWLEDGMENT

The author wishes to express his grateful appreciation to Prof. S. Timoshenko for his valuable suggestions and criticisms.

Graphical Analysis of Impact of Elastic Bars

By K. J. DeJUHASZ,[1] STATE COLLEGE, PA.

The object of this paper is to apply the methods of graphical analysis to the problem of longitudinal central impact of elastic bars, partly to compare the results of the graphical procedure with those arrived at mathematically, and partly to treat complicated cases not readily amenable to mathematical treatment.

THE group of problems on elastic impact to be discussed has a long history in the literature of engineering mechanics, which has been reviewed briefly by Timoshenko.[2] In the usual mathematical treatment, it has been assumed that the stress condition of the body is the same throughout the body at any given instant, i.e., the waves of stress and velocity are propagated with infinite velocity. This is tantamount to the assumption of a perfectly rigid body, i.e., a body incapable of storing potential energy. Yet on the other hand, it has been assumed that the transmission of energy from one body to the other takes place by means of elastic forces.

It has been found that experimental results agree with theoretical deductions in such cases in which the energy before and after the impact is purely in kinetic form. However, important deviations have been found in such cases where, after the impact, one or both of the impacting bodies contained potential energy in the form of traveling waves, according to Ramsauer.[3] Also, it has been recognized by several authors that this discrepancy is due to the contradiction in the basis of the theory mentioned. A more satisfactory theory was sought by assuming (correctly) a finite velocity of stress propagation. Important analytical work has been done on this basis by Saint Venant and Boussinesq,[4] who have treated the case of a body falling on the end of a long bar, supported by an infinite mass.

The mathematical difficulties are, however, of a high order and prevent the clear visualization and understanding of the phenomenon. Furthermore, some important questions, such as those relating to the energy state of the impacting bars after the impact, have remained unanswered.

A way out of the mathematical difficulties was sought, as in other engineering problems, by the use of graphical methods, by means of which important progress has been made by Donnell[5] and Bergeron.[4] The further development of the graphical method has been aided by the fact that several other types of similar engineering problems, such as surges in mechanical springs, in hydraulic systems, and in electric conduits have been solved by graphical means. As a result, the graphical method of analysis has been developed to a considerable degree of refinement, offering a clarity of visualization and adaptability of application unattainable by mathematical analysis.[6, 7, 8, 9] This method may

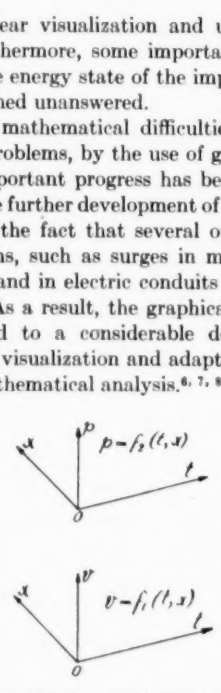

FIG. 1 CO-ORDINATE SYSTEM OF STEREOGRAMS OF STRESS AND VELOCITY AS FUNCTIONS OF TIME AND DISTANCE

be termed "graphic dynamics," because it bears a similar relationship to the mathematical dynamics as does the method of "graphic statics" to mathematical statics.

ESSENTIAL CONCEPTS OF THE GRAPHICAL METHOD

The derivation of the graphical method is fully given in the references.[4–9] However, in order to make this paper self-contained and obviate the necessity of referring to previous literature, a brief summary of the concepts and procedures of graphical analysis, as applied to elastic bars, will be given; the derivation of the formulas will be given in the Appendix.

The purpose of our inquiry is to describe the change of state

in every cross section of an elastic bar, for every instant of time. In accomplishing this purpose, we deal with two co-ordinate systems:

(*a*) The $t - x$ diagram, in which a point identifies an instant of time t, as reckoned from a reference instant, and a cross section of the bar, situated at the distance x, as measured from a reference cross section.

(*b*) The $v - p$ diagram in which a point identifies an "elastic state," i.e., coexisting values of velocity and stress. We restrict our inquiry to cases in which the v, p values are the same at any point of a given cross section, which is tantamount to saying that the cross sections remain plane and parallel to each other at every instant of time.

Thus, the problem resolves into assigning a point in the $v - p$ diagram to every point in the $t - x$ diagram. If this is accomplished, then a pair of three-variable functions

$$v = f_1(t, x) \quad \text{and} \quad p = f_2(t, x)$$

can be derived which can be represented graphically by a pair of tridimensional diagrams, called "stereograms," showing the values of velocity and stress, respectively, erected over the time-distance, $t - x$ plane, as base, Fig. 1.

Such a pair of stereograms (if actually built of wood or plaster) describe completely the change of velocity and of stress in the elastic bar. Thus a section of the stereograms with an x = constant plane will give the velocity (or stress) values at that given cross section in the bar for every instant of time; such a section will be referred to as a "history diagram." A section of the stereograms with a t = constant plane will give the velocity (or stress) values at that particular instant for all cross sections in the bar; such a section will be referred to as a "gradient diagram."

The course of a phenomenon will depend upon a number of data, namely:

(*a*) The design data of the bar, i.e., its cross-sectional area F, and length L.

(*b*) The material constants of the bar, defining its elastic properties, i.e., its elastic modulus E (lb-in.$^{-2}$) and acoustic velocity a (in-sec^{-1}).

(*c*) The characteristics of the disturbance, involving the knowledge of the initial state v_1, p_1 before the disturbance, and the state v_2, p_2 after the disturbance.

There are two important relationships on which the graphical analysis is based, one referring to the $t - x$ diagram, the other to the $v - p$ diagram, as follows:

1 In an elastic bar a disturbance (i.e., change of an existing v_1, p_1 state to another v_2, p_2 state) is propagated along the bar with a constant velocity, which is the acoustic velocity

$$\frac{\Delta x}{\Delta t} = \text{const} = \pm a = \tan(\pm \varphi) \ldots\ldots\ldots [1]$$

This relationship is represented in the $t - x$ diagram by straight lines, called "disturbance lines," having a constant slope, tan ($\pm \varphi$) toward the t axis, Fig. 2. The slope is positive for disturbances in which with increasing time the x co-ordinate increases, and negative for disturbances in which, with increasing time the x co-ordinate decreases. The value of acoustic velocity for steel is a = 208,000 in-sec^{-1}.

2 In an elastic bar, a change of velocity involves a proportional change of stress, and vice versa

$$\frac{\Delta p}{\Delta v} = \text{const} = \pm \frac{E}{a} = \tan(\pm \alpha) \ldots\ldots\ldots [2]$$

which may be termed the "surge constant."

This relationship is represented in the $v - p$ diagram by straight lines, termed "directrixes," having a constant slope, tan ($\pm \alpha$) toward the v axis, Fig. 3. The slope is positive for a disturbance in which the velocity and stress both increase or both decrease; the slope is negative whenever the stress increases with decreasing velocity, or the stress decreases with increasing velocity. For steel E = 31,250,000 lb-in.$^{-2}$ and the surge constant is 151 lb-in.$^{-3}$ sec. This means that a velocity change by 1 in-sec^{-1} imposed on a steel bar is accompanied by 151 lb-in.$^{-2}$ change in the stress.

The validity of these relationships is restricted to such stress values which lie below the elastic limit of the material (for steel of the order of 30,000 lb-in.$^{-2}$), and to such values of velocity which are far below the acoustic velocity. Furthermore, it is assumed that all changes are perfectly elastic in nature, and no dissipation of energy due to hysteresis, damping, or friction takes place.

Energy in the Bar

Areas $v \cdot p$ in the $v - p$ diagram have the dimension of lb-in.$^{-1}$ sec^{-1}, i.e., that of work absorbed by or liberated by a bar of unit

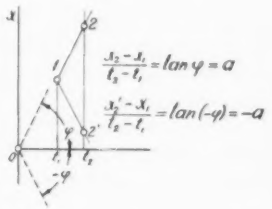

FIG. 2 PROPAGATION OF A DISTURBANCE ALONG AN ELASTIC BAR

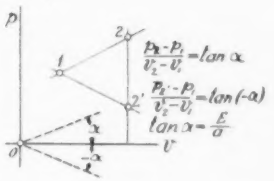

FIG. 3 VELOCITY-STRESS RELATIONSHIP IN AN ELASTIC BAR

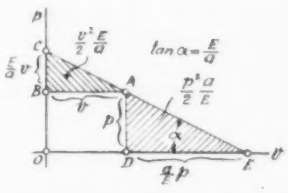

FIG. 4 KINETIC ENERGY AND POTENTIAL ENERGY IN AN ELASTIC BAR

cross-sectional area during 1 sec. As during 1 sec a length a is affected by a change, therefore, it is also correct to say that an area represents the work absorbed or liberated by a bar of unit cross-sectional area having a length a. Triangular areas, defined by a directrix drawn from a v_1, p_1 state (point A, Fig. 4) to the intersection of the v and p axes, represent the potential and kinetic energy, respectively, contained in the bar of unit cross-sectional area and length a, in virtue of its stress p and velocity v. Thus, in Fig. 4, the potential energy of the bar of unit cross-sectional area and of length a, having a stress p_A (point A) is represented by the hatched triangle ΔADE

$$H_p = \frac{p^2}{2}\frac{a}{E} = \Delta ADE$$

and the kinetic energy by the hatched triangle ΔABC

$$H_v = \frac{v^2}{2}\frac{E}{a} = \Delta ABC$$

For a length of bar L, of unit cross section, the corresponding energy values will be L/a times the hatched areas

$$U_p = \frac{L}{a}\,\Delta ADE; \quad U_v = \frac{L}{a}\,\Delta ABC$$

L/a being the interval of time necessary for a disturbance to travel from one end of the bar to the other end.

These properties of the $v - p$ diagram are useful for determining the energy content of the bar, by multiplying the areas of the proper triangles with the cross-sectional area of the bar, and the length portions characterized by the given v, p co-ordinates.

The derivation of the formulas included in this section is given in the Appendix.

Characteristics of Elastic Impact

The impact of elastic bars is characterized by the following facts:

1 While they are in contact with each other, the infinitesimal end slices of the two bars have a common velocity; hence their velocity relative to each other is zero.

2 From (1) it follows that there is no acceleration between the contacting surfaces; hence the forces acting on the contacting cross sections are equal and opposite in the two bars.

3 From (1 and 2), it follows that the state of both bars at the cross section of contact is defined by the same v and the same $P = F_1 p_1 = F_2 p_2$ values, where F_1 is the cross-sectional area of one bar, and F_2 is that of the other. For this reason, it is advantageous to represent the impact in $v - P$ instead of $v - p$ diagrams, because then, for the contacting cross sections, the v, P point will be the same. The directrixes then will be, for the bar with F_1, E_1, a_1 characteristics

$$\tan \alpha_1 = \frac{F_1 E_1}{a_1}$$

and for the bar with F_2, E_2, a_2 characteristics

$$\tan \alpha_2 = \frac{F_2 E_2}{a_2}$$

4 A free end of a bar is characterized by $P = 0$; an end of a bar in contact with an infinite mass is characterized by $v = 0$.

In possession of the relationships (1–4), we are able to proceed to the graphical solution of a number of representative impact problems.

Example 1 Impact of Bar Against Infinite Mass

Referring to Fig. 5, assume a bar AB of F cross-sectional area and L length, with elastic modulus E and acoustic velocity a. The bar is supported without friction in such a manner that it can move only longitudinally, and parallel with itself (e.g., by two bifilar suspensions from points C and D); it has initially zero stress, $P = 0$, and a v_1 velocity. Velocity to the right is chosen as positive, to the left, negative; compressional force is chosen as positive, tensional force, negative. At $t = t_1$ instant, the bar comes into contact with an infinite mass. This disturbance is characterized by the velocity becoming zero. In virtue of the relationship

$$\frac{\Delta P}{\Delta v} = \frac{EF}{a} = \tan (\pm \alpha)$$

this disturbance is represented in the $v - P$ diagram by a tan $(-\alpha)$ directrix drawn from the point 1 and intersecting the $v = 0$ line at point 2, defining the state of the bar at the B point at the $t = t_1$ instant. This disturbance travels toward the other end A of the bar with the acoustic velocity a, represented in the $t - x$ diagram by the slope tan φ, and attains the end A after the elapse of L/a interval. The A end is free and unrestricted, therefore, the value of P is zero; thus the state 2 is changed to

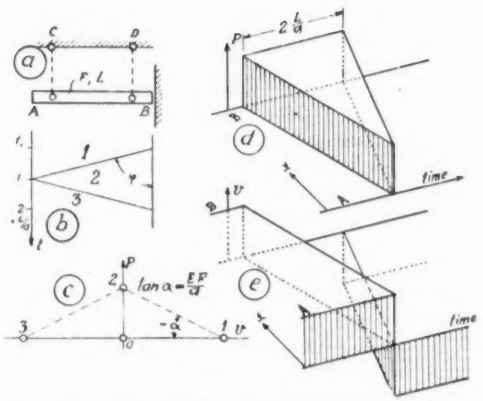

Fig. 5 Impact of Bar Against Infinite Mass
(*a* Schematic arrangement; *b* disturbance diagram; *c* velocity-force diagram; *d* stereogram of force; *e* stereogram of velocity.)

state 3, situated at the intersection of the tan α directrix drawn from point 2 with the $P = 0$ line. This disturbance travels toward the cross section B which it reaches after the elapse of another L/a interval of time. Erecting the v and P co-ordinates of the 1–2–3 points over the respective zones of the $t - x$ diagram, the stereograms of force and velocity are obtained, Fig. 5 (d, e). It is seen that the velocity after the impact is equal and opposite to that before the impact. It is of course evident that the postulata of conservation of momentum and of energy are satisfied.

Example 2 Impact of Moving Bar Against Similar Bar at Rest

Referring to Fig. 6, the values of E, a, and F being the same for both bars, the value of tan φ and of tan α is the same for both. In the $v - P$ diagram, the initial state of the bar AB is defined by point 1a and that of CD by point 1b, Fig. 6(c). When at the $t = t_1$ instant the two bars come into contact the velocity of the cross section B is reduced, and that of C is increased to the value corresponding to point 2 situated at the intersection of the tan $(-\alpha)$ directrix drawn from the point 1a with the directrix tan $(+\alpha)$ drawn from point 1b. The force is thereby increased from zero to that defined by point 2. This disturbance travels from B to A and from C to D with the acoustic velocity a and reaches the cross sections A and D, respectively, after the elapse of L/a interval of time. The state at both A and D is characterized by $P = 0$, therefore another disturbance takes place, defined for the cross section A by the point 3a situated at the intersection of the directrix tan $(+\alpha)$ drawn from point 2 with the $P = 0$ line, and for the cross section D by the point 3b situated at the intersection of the directrix tan $(-\alpha)$ drawn from point 2 with the $P = 0$ line. After the elapse of a further L/a interval these respective states will have traveled to the B and C cross sections, respectively, and the total bar AB will be at rest (point 3a), and the total bar CD will have the velocity 3b, which is of course equivalent to the initial velocity of bar AB. The stereograms of velocity and force are given in Fig. 6(d, e), from which for any cross section of the two bars the history of velocity and of force can be determined.

This problem has been also investigated experimentally by Fanning and Bassett,[10] and the oscillograms obtained confirm

[10] "Measurement of Impact Strains by Carbon-Strip Extensometer," by R. Fanning and W. V. Bassett, Journal of Applied Mechanics, Trans. A.S.M.E., vol. 62, 1940, p. A-24. The stress-time curve in an elastic bar, when the bar is struck by another bar, is determined by a resistance strain gage in conjunction with an oscillograph.

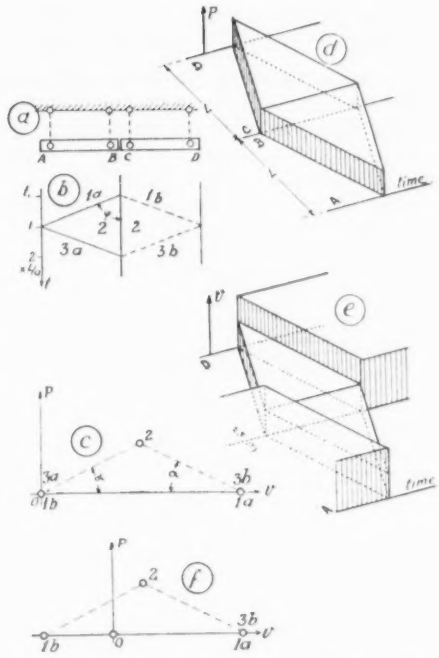

FIG. 6 IMPACT OF MOVING BAR AGAINST A SIMILAR BAR AT REST
(*a*, Schematic arrangement; *b*, disturbance diagram; *c*, velocity-force diagram; *d*, stereogram of force; *e*, stereogram of velocity; *f*, velocity-force diagram for both bars having an initial velocity.)

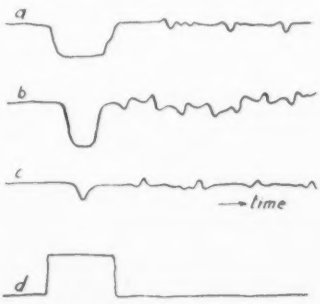

FIG. 7 OSCILLOGRAMS OF STRAINS IN IMPACTED BAR BY FANNING AND BASSETT
(*a*, Strains near impacted end; *b*, strains in middle of bar; *c*, strains at far end of bar; *d*, duration of electric contact at the contacting point of impact. The two bars were 6 ft long, and had the same cross-sectional area, having the impact end formed as a hemisphere.)

the results of the graphical analysis, Fig. 7. The deviation is due to the fact that, in the experimental arrangement, the two bars had a hemispherical shape at their impacting end. It is seen that the impacting and impacted bars exchange their velocities, and this is the case even when the bar *CD* has other than zero initial velocity, Fig. 6 (*f*).

EXAMPLE 3 IMPACT OF SHORT MOVING BAR AGAINST LONG BAR AT REST

In Fig. 8, it is assumed that the two bars have the same *E*, *a*, and *F* (hence tan α) values, but bar *CD* is twice as long as bar *AB*. The procedure and the $v - P$ diagram are similar to those in example 2. After the conclusion of the impact, the bar *AB* comes to rest (point 4) but bar *CD* does not attain a state of equilibrium. It goes through changes of velocity and force, the kinetic energy being converted into potential energy and vice versa, according to points 3–4–5–. . . . 11 in the $v - P$ diagram, which are valid in the similarly denoted zones of the $t - x$ diagram. In addition to the two stereograms, Fig. 8 (*d*, *e*), also the history of velocity for the end *C* is drawn Fig. 8 (*f*). It is seen that the velocity alternates between the value point 1 (original velocity of bar *AB*) and zero, each lasting for an L/a interval. The mean velocity is therefore one half of the original velocity of bar *AB*. The same value of mean velocity prevails for every cross section of the bar *CD*, as can be easily proved by intersecting the velocity stereogram with various x = constant planes.

It is of interest to compare this result with that obtained from mathematical theory for the elastic impact of point masses, according to which

v_1 = initial velocity of m_1 mass
v_2 = initial velocity of m_2 mass
v_1' = velocity after impact of m_1 mass
v_2' = velocity after impact of m_2 mass

$$v_1' = \frac{(m_1 - m_2)v_1 + 2m_2v_2}{m_1 + m_2}$$

$$v_2' = \frac{2m_1v_1 - (m_1 - m_2)v_2}{m_1 + m_2}$$

In example 3 $v_2 = 0$ and $m_2 = 2m_1$, hence

$$v_1' = -\frac{v_1}{3} \quad \text{and} \quad v_2' = \frac{2}{3}v_1$$

The surprising thing is that the graphical method yields a different result from the mathematical method. The former is

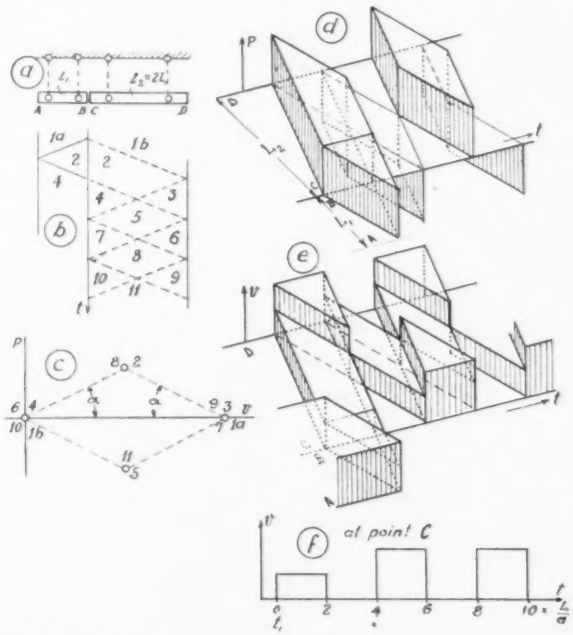

FIG. 8 IMPACT OF SHORT MOVING BAR AGAINST LONG BAR AT REST
(*a*, Schematic arrangement; *b*, disturbance diagram; *c*, velocity-force diagram; *d*, stereogram of force; *e*, stereogram of velocity; *f*, history of velocity at cross-section *D*.)

correct, and the latter is in error, owing to the assumption of infinite velocity of propagation of the disturbance, i.e., neglect of energy stored in the form of traveling waves. It will be shown in a later example that in particular cases the mathematical method and graphical method yield identical results.

EXAMPLE 4 IMPACT OF THREE BARS HAVING THE SAME CROSS SECTION

In Fig. 9, it is assumed that bar *AB* is moving with velocity v_1, bars *CD* and *EF* are at rest, and that they are in contact with each other. Bars *AB* and *EF* have the same length; the intermediate bar *CD* has a different length. From the $t - x$ and

$v - p$ diagrams, it can be seen that after the impact the impacting bar AB and the middle bar CD remain at rest, and the last bar EF receives the total velocity (and momentum, and energy) of AB. This result would be obtained regardless of the length of the interposed bar CD, or even if more than one bar is interposed,

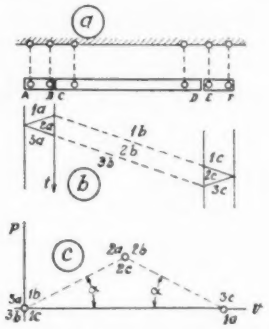

FIG. 9 IMPACT OF THREE BARS HAVING THE SAME CROSS SECTION
(a, Schematic arrangement; b, disturbance diagram; c, velocity-force diagram.)

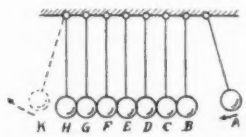

FIG. 10 EXPERIMENTAL ARRANGEMENT OF ROW OF BALLS WITH BIFILAR SUSPENSION
(When ball A is lifted and released and impacts against ball B, the last ball K will swing out, the others remaining at rest.)

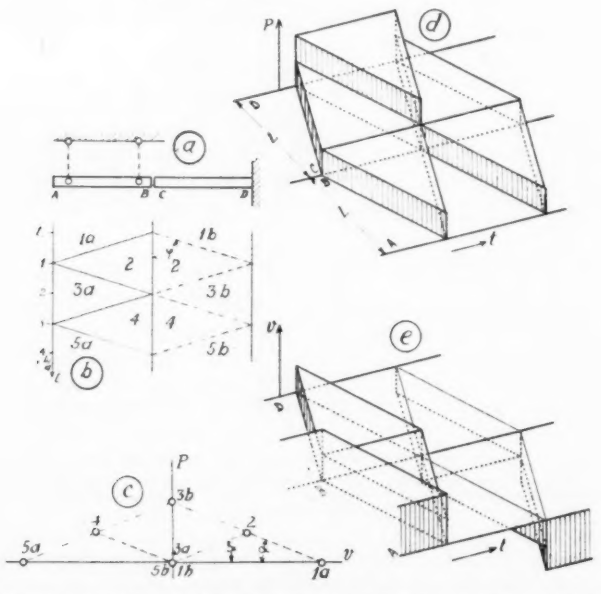

FIG. 11 IMPACT OF MOVING BAR AGAINST SIMILAR BAR AT REST, FIXED TO AN INFINITE MASS
(a, Schematic arrangement; b, disturbance diagram; c, velocity-force diagram; d, stereogram of force; e, stereogram of velocity.)

provided that the cross section of all bars is the same, and the first and last bars have the same length. This case is equivalent to the classic experiment of a row of contacting balls supported by bifilar suspension; lifting and releasing the first ball the last ball will swing out, the intermediate balls remaining at rest, Fig. 10.

EXAMPLE 5 IMPACT OF MOVING BAR AGAINST SIMILAR BAR AT REST, FIXED TO AN INFINITE MASS

In Fig. 11, the assumptions, reasoning, and procedure are similar to those of example 2, except for the fact that the cross section D of bar CD is fixed to an infinite mass, and therefore its velocity is zero at all times. The $t - x$ and $v - p$ diagrams are shown in Fig. 11 (b, c), and the resulting stereograms of velocity and force in Fig. 11 (d, e). It is seen that, after the conclusion of the impact, the bar AB has a velocity equal and opposite to

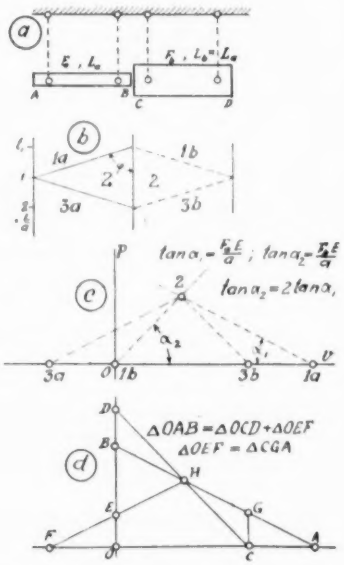

FIG. 12 IMPACT OF MOVING BAR AGAINST STATIONARY BAR HAVING THE SAME LENGTH AND DOUBLE CROSS SECTION
(a, Schematic arrangement; b, disturbance diagram; c, velocity-force diagram; d, energy diagram.)

the initial value (point 5a), which is, of course in full agreement with the mathematical analysis and experimental results.

EXAMPLE 6 IMPACT OF MOVING BAR AGAINST STATIONARY BAR HAVING SAME LENGTH AND DOUBLE CROSS SECTION

In the case shown in Fig. 12, the slope of the directrix of bar CD has double the value of that of bar AB

$$\text{For } AB, \tan \alpha_1 = \frac{EF_a}{a}; \quad \text{for } CD, \tan \alpha_2 = \frac{EF_b}{a} = 2 \tan \alpha_1$$

The $t - x$ and $v - P$ diagrams are shown in Fig. 12 (b, c). It is seen that after the impact the velocity of $AB = -\frac{1}{3} v_1$ and that of $CD = \frac{2}{3} v_1$. In this case, there remains no residual potential energy in the bar CD (as was the case in example 3), and the result of mathematical calculation is correct.

The initial energy of bar AB is represented in Fig. 12 (d) by $\frac{L}{a} \Delta OAB$, the energy of AB after the impact by $\frac{L}{a} \Delta OEF$, and that of bar CD by $\frac{L}{a} \Delta OCD$. It is seen that $\Delta OAB = \Delta OEF + \Delta OCD$.

EXAMPLE 7 IMPACT OF MOVING BAR AGAINST STATIONARY BAR FIXED TO INFINITE MASS, THE TWO BARS HAVING DIFFERENT LENGTHS AND CROSS-SECTIONAL AREAS

In Fig. 13, it is assumed that bar AB has a length L_a and cross

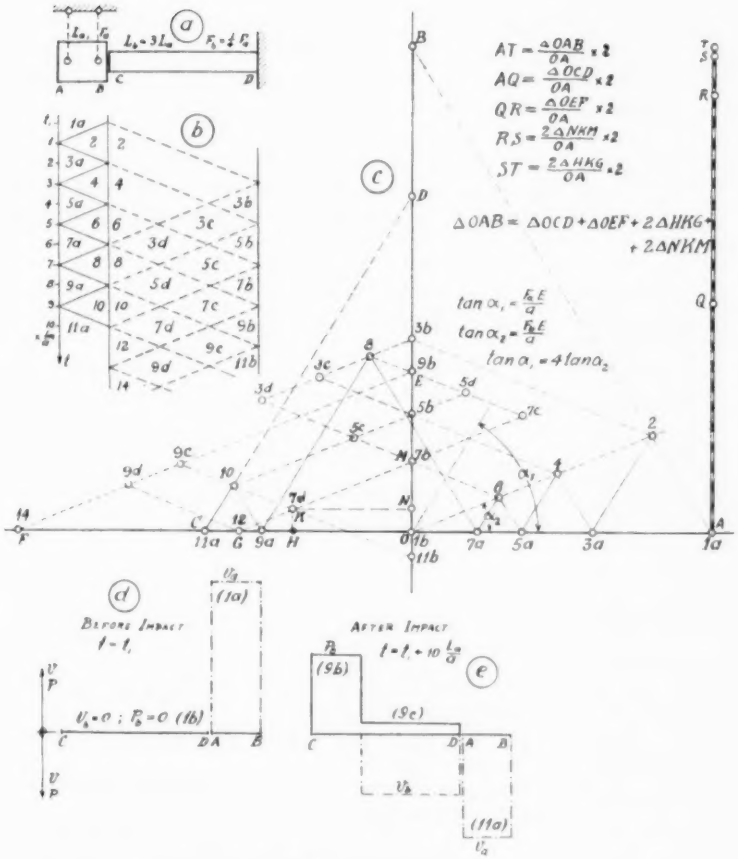

FIG. 13 IMPACT OF MOVING BAR AGAINST STATIONARY BAR FIXED TO INFINITE MASS, THE TWO BARS HAVING DIFFERENT LENGTHS AND CROSS-SECTIONAL AREAS

(*a*, Schematic arrangement; *b*, disturbance diagram; *c*, velocity-force diagram; *d*, state of bars before impact; *e*, state of bars after impact; *f*, stereogram of force; *g*, stereogram of velocity.)

section F_a; bar CD has a length $3L_a$ and cross-sectional area $^1/_4F_a$. Therefore, the slope of the directrix of bar AB is 4 times that of CD.

$$\tan\alpha_1 = \frac{EF_a}{a}; \quad \tan\alpha_2 = \frac{EF_b}{a} = {}^1/_4\tan\alpha$$

and the time interval of traverse in the bar CD is 3 times longer than in bar AB. The $t - x$ and $v - P$ diagrams are shown in Fig. 13 (*b*, *c*) from which the stereograms of velocity and of force can be constructed without difficulty, Fig. 13 (*f*, *g*). After the tenth L/a interval, the bar AB has the velocity denoted by point 11*a* and the impact is concluded. But the bar CD does not remain at rest; in it remain surges, $2L$ portion of it having the velocity and force according to point 7*d*, and $1L$ portion of it having a compression, according to point 9*b*. Fig. 13 (*d*) gives the state of both bars before the impact, and Fig. 13 (*e*) after the impact at the $t_1 = 10\,\frac{L_a}{a}$ instant. As these states are not in equilibrium, therefore, conversion of potential into kinetic energy and vice versa takes place in the successive intervals, as denoted in the $t - x$ diagram and in the $v - P$ diagram by identical figures. It can be proved, however, that the sum of the energies in bars AB and CD after the impact is equal to the initial kinetic energy of bar AB before the impact.

Referring to the derivations given earlier in this paper, the energies can be expressed as triangles in the $v - P$ diagram. Thus the initial kinetic energy of the bar AB is equivalent to $\frac{L}{a}\,\Delta OAB$; the final kinetic energy is equivalent to $\frac{L}{a}\,\Delta OCD$. For the CD bar, the potential energy corresponding to state 9*b* is

equivalent to $\frac{L}{a}\ \Delta OFE$. A $2L$ portion has the state $7d$, having both potential and kinetic energies: The potential energy is equivalent to $\frac{2L}{a}\ \Delta HKG$, and the kinetic energy is equivalent to $\frac{2L}{a}\ \Delta NKM$. By simple planimetering or counting of squares in the actual diagram, it can be proved that

$$\Delta OAB = \Delta OCD + \Delta OEF + 2\Delta HKG + 2\Delta NKM$$

or, clearer yet, these triangles can be converted by a simple graphical construction into equal-area triangles having the same base, e.g., the base OA. Then the areas will be proportional to the respective heights

$$AT = \frac{\Delta OAB}{OA/2};\ AQ = \frac{\Delta OCD}{OA/2};\ QR = \frac{\Delta OEF}{OA/2};\ RS = \frac{2\Delta NKM}{OA/2};$$

$$ST = \frac{2\Delta HKG}{OA/2}$$

from which it can be seen that

$$AT = AQ + QR + RS + ST$$

which is an added proof of the correctness of the graphical method.

A problem of such complexity is beyond the applicability of mathematical calculation, yet it can be treated without difficulty by the graphical method. Even more involved cases, composed of a number of impacting bars, each having different lengths, cross-sectional areas, and elastic properties, as well as different initial velocities, are well within the scope of applicability of the graphical treatment.

Appendix

Derivation of Basic Equations of Graphical Analysis

Assume an elastic bar, Fig. 14 (a), of modulus of elasticity E, specific volume V, of unit cross-sectional area, initially having v_1

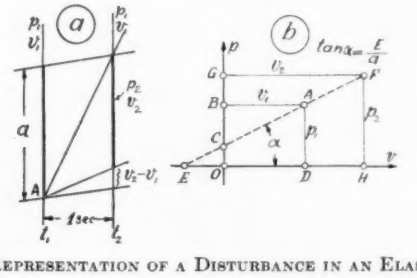

Fig. 14 Representation of a Disturbance in an Elastic Bar (a, History of change of state; b, velocity-stress diagram of disturbance.)

velocity and p_1 stress in its every cross section. At the instant t_1 the velocity is changed to v_2 at the point A. Thereby, the stress is changed to p_2 (the value of which is as yet unknown). The new state v_2, p_2 represents a disturbance which is propagated with constant velocity a (the value of which is yet unknown). After 1 sec has elapsed, a length a of the bar will have assumed the new state v_2, p_2. It is our purpose to determine p_2 and a.

After the elapse of 1 sec, the initial a length of the bar is changed to $a - (v_2 - v_1)$, and it can be written

$$\frac{a - (v_2 - v_1)}{a} = \frac{E - p_2}{E - p_1}$$

Assuming an elastic change, in which the values of p_2 and p_1 are very small in comparison with E, it can be written

$$1 - \frac{v_2 - v_1}{a} = 1 - \frac{p_2 - p_1}{E}$$

Denoting $p_2 - p_1 = \Delta p$ and $v_2 - v_1 = \Delta v$ it can be written

$$\frac{\Delta p}{\Delta v} = \frac{E}{a} \quad \ldots\ldots\ldots\ldots\ldots\ldots [3]$$

giving one fundamental equation of the graphical method.

From the postulatum of conservation of momentum, it can be written

$$(p_2 - p_1)\,\Delta t = m(v_2 - v_1)$$

Denoting $\Delta t = 1$ sec; $m = \frac{a}{V}$

which can be written $\Delta p = \frac{a}{V}\,\Delta v$

whence $\frac{\Delta p}{\Delta v} = \frac{a}{V}$

Combining with Equation [3] we obtain

$$\frac{a}{V} = \frac{E}{a}$$

whence $a = \sqrt{VE}$

giving the value of the velocity of propagation in terms of the properties of the material.

It is to be shown that these relationships satisfy the postulatum of conservation of energy.

For a length of bar a having co-ordinates of state v, p the energies can be expressed

$$\text{Kinetic energy} = Hv = \frac{mv^2}{2} = \frac{a}{V}\frac{v^2}{2} = \frac{E}{a}\frac{v^2}{2}$$

$$\text{Potential energy} = Hp = \frac{ap}{E}\frac{p}{2} = \frac{a}{E}\frac{p^2}{2}$$

that is, expansion of bar from p stress to zero stress, by a travel $a\frac{p}{E}$. If the initial state is $p = 0$, $v = 0$, then $p = \frac{E}{a}v$ and the kinetic energy is equal to the potential energy.

When the state of the bar is changed from state v_1, p_1 to state v_2, p_2 the work done per second (on length a because during 1 sec a length a of the bar is affected) is p_2v_2. Part of this work is expended in moving the bar against p_1 stress with v_1 velocity, i.e., p_1v_1. The balance appears as the change of kinetic plus potential energies in the bar. It can be written

$$p_2v_2 - p_1v_1 = \frac{1}{2}\frac{E}{a}(v_2^2 - v_1^2) + \frac{1}{2}\frac{a}{E}(p_2^2 - p_1^2)$$

$$= \frac{1}{2}\frac{E}{a}(v_2 - v_1)(v_2 + v_1) + \frac{1}{2}\frac{a}{E}(p_2 - p_1)(p_2 + p_1)$$

Substituting $p_2 - p_1 = \frac{E}{a}(v_2 - v_1)$

$$p_2v_2 - p_1v_1 = \frac{1}{2}(p_2 - p_1)(v_2 + v_1) + \frac{1}{2}(v_2 - v_1)(p_2 + p_1)$$

which expanded leads to an identity, q.e.d.

In the $v - p$ diagram for a length of bar a the kinetic energy is represented, for v_1, p_1 state (point A, Fig. 14) by the triangle ΔABC; and the potential energy by the triangle ΔADE. Similarly, for the v_2, p_2 state (point F) the respective triangles are ΔFGC and ΔFHE. It is readily seen that the difference $p_2v_2 - p_1v_1$ is $FGOH - ABOD = ABGFHD$.

Some Dynamic Properties of Rubber

By C. O. HARRIS,[1] CHICAGO, ILL.

The purpose of the investigation[2] described in this paper was to obtain information concerning the dynamic properties of rubber bonded to metal. Two properties of rubber were measured (*a*) the internal damping and (*b*) the dynamic modulus of elasticity. Two types of specimens were tested (*a*) rubber cylinders bonded to steel cylinders at the ends and stressed in compression and (*b*) specimens of rubber bonded to steel and stressed in shear. All specimens were of the same stock, 5140-V-4, manufactured by the U. S. Rubber Company. The hardness, as measured by the durometer, varied from 32 to 40. In the process of bonding to the steel, a $^1/_{32}$-in. layer of 60-durometer stock was added adjacent to each piece of steel. This represents standard practice of the U. S. Rubber Company in bonding soft stock to metal. All specimens were cured for 30 min at 279 F.

Previous Work

Kosten[3] tested massive rubber cylinders under forced vibrations. Three ratios of diameter to length were used, namely, 1, $^1/_2$, and $^1/_4$. All were tested in compression. He assumed a viscous damping and found that the product of frequency and damping coefficient was constant. He introduced the angle of loss as a variable. It is defined as $\tan^{-1}\frac{cp}{k}$, where c, p, and k represent damping coefficient, angular frequency, and spring constant, respectively. He concluded that:

1 The modulus of elasticity as calculated from dynamic tests is larger than the static modulus.

2 The dynamic modulus is independent of frequency.

3 The angle of loss has a tendency to increase with frequency and load.

Naunton and Waring[4] used a moving-coil driver unit which applied an alternating stress to two cylinders of rubber, each having a diameter of twice the length, placed on either side of a diaphragm attached to the moving coil. The system was tuned to resonance, and all calculations were made from measurements of amplitude and frequency at resonance. The following conclusions were reached:

1 The dynamic modulus of elasticity tends to increase with frequency.

2 The viscous resistance decreases with frequency and tends to become constant at higher frequencies.

Roelig[5] tested cylinders of rubber bonded to metal disks at the ends. The diameter and length were equal in all cases. A coil spring maintained a static load, and a dynamic load was superposed on this by means of an eccentric weight on the shaft of an electric motor. The load was measured by means of a dynamometer, and the displacement was taken as equal to that of the motor. A beam of light was reflected from two mirrors, one mounted on the casing of the motor and one in the dynamometer. This beam of light described a dynamic hysteresis loop on which calculations were based. Quantities measured include:

(1) Δw = energy lost per cycle (area of hysteresis loop).

(2) $\frac{\Delta w}{w}$ = ratio of energy lost to total energy (loop area divided by area between loop and axis of strain).

(3) Dynamic modulus of elasticity.

Roelig concluded that:

(1) Δw increases with increase of dynamic load while $\frac{\Delta w}{w}$ remains constant.

(2) Δw decreases with increase of static load while there is not much change in $\frac{\Delta w}{w}$.

(3) Both Δw and $\frac{\Delta w}{w}$ show a slight increase with increase of frequency.

(4) Δw increases with volume while $\frac{\Delta w}{w}$ decreases.

Of interest in regard to internal damping is a paper by Williams,[6] who states: "Energy expended on raw or vulcanized rubber is consumed largely by producing plastic flow and reversible elastic strain...Stress-strain curves obtained rapidly become straight lines through elimination of plastic flow." From this it would be expected that Δw would decrease with increase of frequency.

Hysteresis and Internal Damping

The energy lost by a unit volume of material in passing through a cycle of stress is equal to the area of the hysteresis loop. On the assumption that this loop maintains a constant shape, the area is proportional to ϵ_0^2 where ϵ_0 is the amplitude of strain. The area may be taken as $F\epsilon_0^2$, term F being a factor dependent upon material, type of stress, etc. For a bar of constant cross section, which has the same stress throughout its length, the total loss in energy is $F\epsilon_0^2$ times the volume, or $F\epsilon_0^2 Al$.

For a member of length l, with one end stationary and the other end subjected to a cyclic displacement of amplitude x_0, the damping force, taken as proportional to the velocity of the moving end, is $C\dot{x}$. The work done by the damping force in one cycle is $\pi C p x_0^2$ where p is the angular frequency of the motion. Equating this to the total hysteresis loss

$$\pi C p x_0^2 = F\epsilon_0^2 Al = F x_0^2 \frac{A}{l}$$

$$\frac{Cl}{A} = \frac{F}{\pi p} = C_2 \quad \ldots\ldots\ldots\ldots\ldots\ldots [1]$$

Coefficient C_2 appears to be very convenient for use in specifying internal damping, since it permits comparison of specimens of different dimensions. Its physical significance may be seen by writing $C = C_2 \frac{A}{l}$ from which the damping force is $C_2 \frac{A}{l} \dot{x} = C_2 A \dot{\epsilon}$. Thus C_2 is a damping coefficient which is to multiply the velocity of strain and the area to give the damping force. Its units are $\frac{\text{lb-sec}}{\text{in.}^2}$. All damping data obtained in this investigation have been expressed by means of C_2. Equation [1] indicates that C_2 is inversely proportional to the frequency, if the hysteresis loop maintains the same shape at all frequencies. Any deviation of C_2 from such inverse proportionality would indicate that the frequency has an effect upon the shape of the hysteresis loop. If different values of C_2 are obtained for specimens of different shape, this would indicate a dependence of the condition of stress upon the shape.

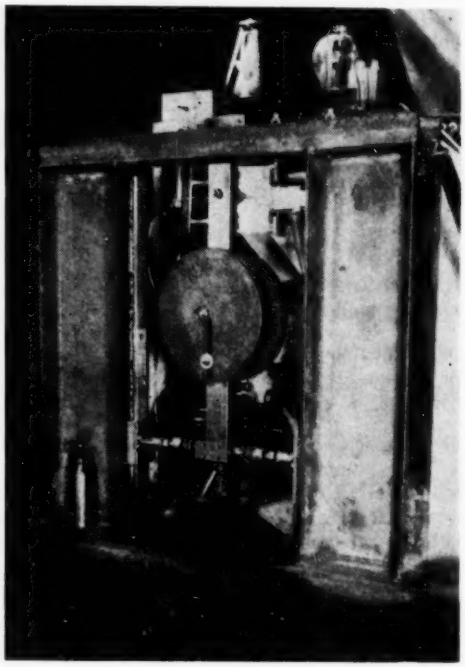

FIG. 1 GENERAL VIEW OF APPARATUS

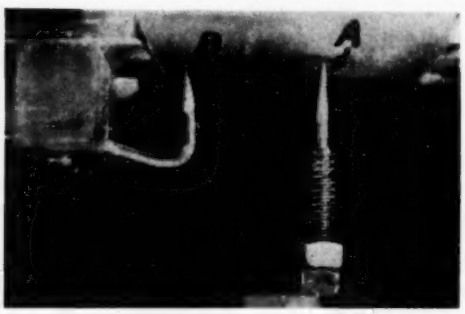

FIG. 2 HIGH-FREQUENCY-SPARK NEEDLES FOR RECORDING MOTION OF PENDULUM AND TIME

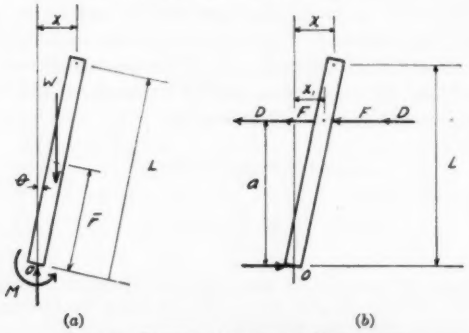

FIG. 3 FORCES ACTING ON PENDULUM
(*a*, Forces acting on pendulum alone; *b*, additional forces due to rubber specimens.)

APPARATUS AND MEASUREMENTS

A dynamic loading was superposed upon a static loading for a pair of specimens by means of a pendulum supported by an elastic hinge. A general view of the equipment is shown in Fig. 1. In this system, the rubber contributed to the damping and to the spring constant.

The rubber specimens were supported by means of conical points seating in conical holes of larger angle in the metal plates to which the rubber was bonded. The conical points on the rectangular frame could be adjusted by means of a screw so that the static deformation of the rubber specimens could be varied.

In order to start a free vibration, the pendulum was pulled to one side and held by means of a pin. Upon pulling out the pin, the pendulum would oscillate in a free vibration. The initial amplitude of the motion could be varied by adjusting the bar which held the pin.

The motion of the pendulum was recorded upon a strip of paper which moved across a metal plate. A needle A, on the end of the pendulum, discharged a high-frequency spark through the paper to the plate. The holes burned in the paper by the spark constituted the record of the motion. In addition, a second needle B discharged a series of sparks each second, giving a time measure. The two needles are shown in their positions adjacent to the paper strip in Fig. 2.

The frequency of the pendulum could be varied appreciably in three ways:

1 By changing the distance of the rubber specimens from the axis of rotation of the pendulum.

2 By adding auxiliary springs to the system.

3 By adding weights to the pendulum. One pair of weights appears in Fig. 1.

The natural frequency of the pendulum alone varied from 1.15 to 34.8 cycles per sec. The lowest frequency recorded for a vibration with rubber specimens was 3.93 cycles per sec; the highest was 46.2 cycles per sec.

The forces acting on the pendulum alone are shown in Fig. 3 (*a*). The moment about the axis of rotation exerted by the elastic hinge is proportional to the angular displacement and is $-k\theta$. If the damping is taken as proportional to the angular velocity of the pendulum, the moment due to damping is $-k_1\dot{\theta}$. The equation of motion for the pendulum is

$$I_0\ddot{\theta} = W\bar{r}\theta - k\theta - k_1\dot{\theta} \quad \ldots\ldots [2]$$

Since the linear displacement x is the quantity measured, it is best to change variables. For small displacements

$$\theta = \frac{x}{l}; \quad \dot{\theta} = \frac{\dot{x}}{l}; \quad \ddot{\theta} = \frac{\ddot{x}}{l}$$

Substituting

$$\ddot{x} + \frac{k_1}{I_0}\dot{x} + \frac{(k - W\bar{r})}{I_0}x = 0$$

This equation can be changed to standard form by letting $2q = \frac{k_1}{I_0}$ and $p^2 = \frac{k - W\bar{r}}{I_0}$. Then

$$\ddot{x} + 2qx + p^2\dot{x} = 0 \quad \ldots\ldots [3]$$

The solution of Equation [3] is

$$x = x_0 e^{-qt}\left(\cos\sqrt{p^2 - q^2}\,t + \frac{q}{\sqrt{p^2 - q^2}}\sin\sqrt{p^2 - q^2}\,t\right)$$

in which x_0 is the initial amplitude. For the small damping encountered in this investigation, this is approximately

$$x = x_0 e^{-qt}\cos pt \quad \ldots\ldots [4]$$

When two rubber specimens are added to the system, elastic forces F and damping forces D are exerted on the pendulum, Fig. 3 (*b*). The elastic force for each specimen is $F = \frac{Ex_1A}{l}$, or since $x_1 = \frac{ax}{L}$ then $F = \frac{EAa}{Ll}x$. The quantities E, A, and l are, respectively, modulus of elasticity, area, and length of the specimen. The inner end of the rubber specimen has the same velocity as the point on the pendulum at the distance a from the axis. The outer end is at rest. Assuming that the damping force D is proportional to the velocity of the moving end

$$D = C\dot{x}_1 \quad \text{or} \quad D = C\frac{a}{L}\dot{x}$$

The additional moment due to the rubber specimens is

$$-2\frac{EAa^2}{Ll}x - 2C\frac{a^2}{L}\dot{x}$$

When these terms are added to Equation [2], the following equation can be obtained

$$\ddot{x} + \left(2q + 2\frac{Ca^2}{I_0}\right)\dot{x} + \left(p^2 + 2\frac{EAa^2}{I_0 l}\right)x = 0$$

Putting

$$2q_1 = 2q + 2\frac{Ca^2}{I_0} \quad \ldots\ldots [5]$$

and

$$p_1^2 = p^2 + 2\frac{EAa^2}{I_0 l} \quad \ldots\ldots [6]$$

$$\ddot{x} + 2q_1\dot{x} + p_1^2 x = 0$$

This has for an approximate solution

$$x = x_0 e^{-q_1 t}\cos p_1 t \quad \ldots\ldots [7]$$

Equation [7] represents a cyclic motion with decaying amplitude. It has the period $\frac{2\pi}{p_1}$. The damping was measured in this investigation by means of the relation

$$N = \frac{\text{Amplitude after } n \text{ cycles}}{\text{Initial amplitude}} = e^{-2\pi n q_1/p_1} \quad \ldots\ldots [8]$$

The manner of using it was as follows:

Equation [8] was plotted on semilogarithmic paper (on which it is a straight line) for several values of n, Fig. 4. The quantity N was determined from the record of the vibration for the same values of n. Then each N was plotted on the proper line in Fig. 4. If points so plotted fall in a vertical line, the damping force is proportional to the velocity and the value of q_1/p_1 can be determined immediately. For each test performed in this investigation, the points plotted, as in Fig. 4, could be represented reasonably by a vertical line. The quantity n was increased in increments of 1, 2, or 10, depending upon the rate at which the oscillation died out. The frequency, in cycles per second, of the motion described by Equation [7] can be obtained easily from the vibration record. If this frequency is denoted by f, then $p_1 = 2\pi f$. Term q_1 is the product of q_1/p_1 and p_1. The quantities q and p for the pendulum alone can be determined in the same way as q_1 and p_1. Then from Equations [5] and [6]

$$C = \frac{I_0}{a^2}(q_1 - q)$$

and

$$E = \frac{I_0 l}{2Aa^2}(p_1^2 - p^2)$$

From Equation [1], the damping coefficient C_2 in terms of which the damping data herein obtained have been expressed is $C_2 = \frac{Cl}{A}$.

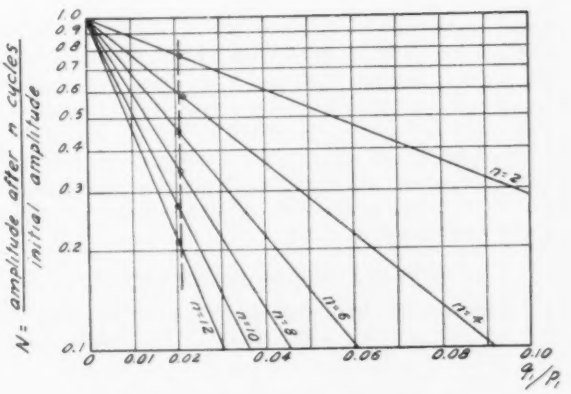

FIG. 4 CHART FOR EVALUATING q_1/p_1

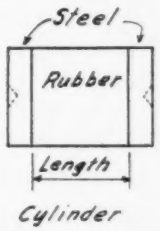

FIG. 5 TYPE OF TEST CYLINDER

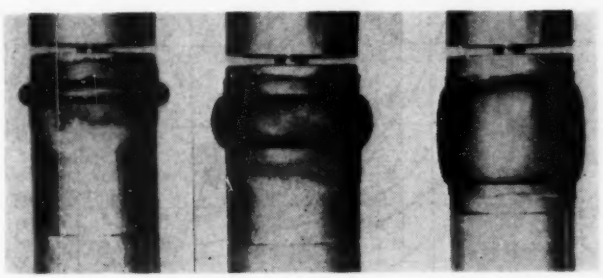

FIG. 6 THREE 1-IN. CYLINDERS

CYLINDERS IN COMPRESSION

Results are given in the following section for 17 pairs of cylinders tested in compression. These include cylinders of 1 in.

diam and lengths of 1 in. (3 pairs), 0.9 in., 0.8 in., 0.7 in., 0.6 in., 0.5 in., 0.4 in., 0.31 in., and 0.21 in.; 1.5 in. diam and lengths of 1.05 in., 0.45 in., and 0.35 in.; 2 in. diam and lengths of 1.05 in., 0.45 in., and 0.35 in. All were bonded to steel disks at the ends and were of the type shown in Fig. 5. Fig. 6 shows three cylinders of 1 in. diam under a strain of approximately 0.25. A pronounced end effect, which depends upon length, is evident. This made it desirable to test cylinders of several lengths for each diameter.

Damping of Cylinders in Compression

Fig. 7 shows the effect of frequency on the damping coefficient C_2 for a number of the cylinders tested. The results indicate

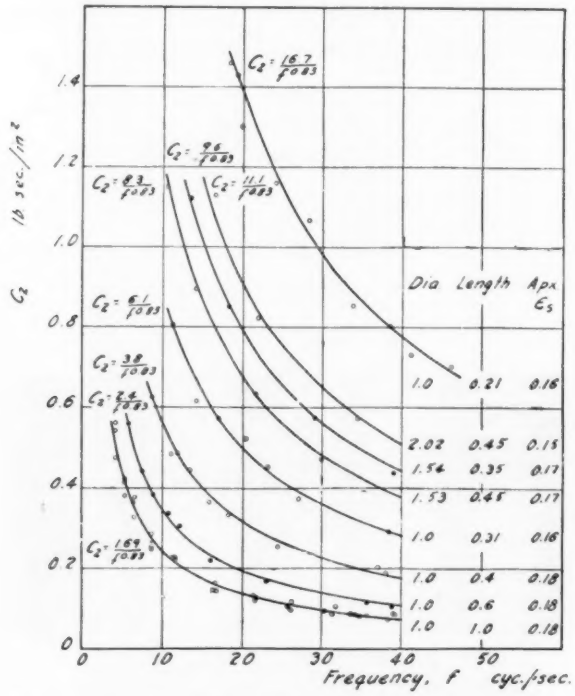

Fig. 7 Effect of Frequency on Damping Coefficient C_2
(Cylinders in compression; ϵ_s = static strain.)

that the damping is inversely proportional to $f^{0.83}$. Additional results are given in Table 1.

TABLE 1 RESULTS OF DAMPING TESTS

Diameter, in.	Length, in.	Approx. ϵ_s	$C_2 f^{0.83}$
1	0.9	0.18	1.64
1	0.5	0.18	2.47
1	0.7	0.18	1.76
1	0.8	0.14	1.76
2	1	0.15	2.12
2	0.35	0.15	16.5
1.5	1	0.17	1.65

The effect of static strain ϵ_s on the damping can be expressed by means of a function $A(\epsilon_s)$. Thus

$$C_2 = \frac{A(\epsilon_s)}{f^{0.83}} \quad \text{or} \quad C_2 f^{0.83} = A(\epsilon_s)$$

Fig. 8 shows the product $C_2 f^{0.83}$ plotted against the static strain for several pairs of cylinders. It appears that a linear relation is satisfactory for values of ϵ_s not exceeding 0.20, that is, $C_2 f^{0.83} = B_0 + B_1 \epsilon_s$, where B_0 is the intercept of the straight line on the vertical axis and B_1 is the slope.

The foregoing results indicate that the configuration of the

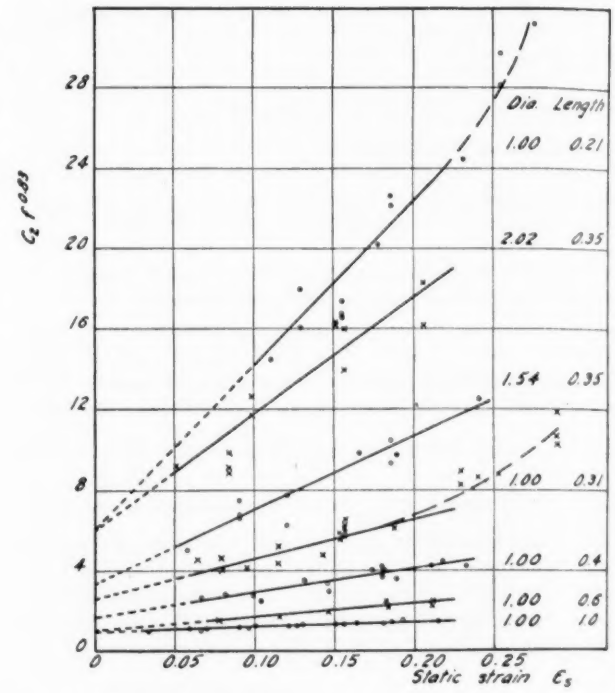

Fig. 8 Effect of Static Strain on Damping Coefficient C_2
(Cylinders in compression.)

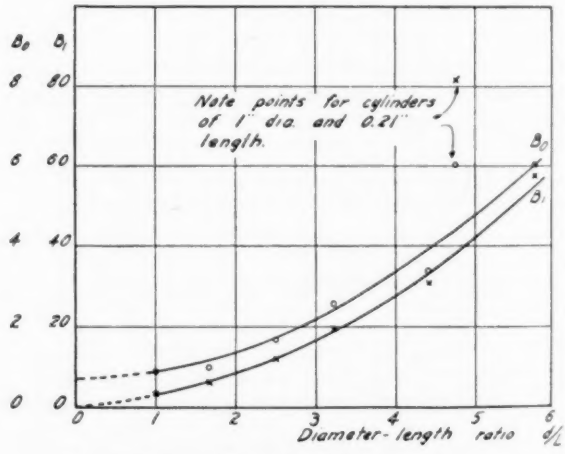

Fig. 9 Factors B_0 and B_1 Plotted Against d/L
(Cylinders in compression.)

cylinder has a considerable effect on the damping. A convenient way of describing the configuration is by means of the diameter-length ratio, d/L. Accordingly, the factors B_0 and B_1 from Fig. 8 have been plotted against d/L in Fig. 9. The factors for the cylinders of 1 in. diam and 0.21 in. length have values which are inconsistent with those for the other cylinders. This may be due to the $^1/_{32}$-in. layer of harder stock at each end. For this length, over 30 per cent of the specimen consists of the harder stock.

Dynamic Modulus of Elasticity

Fig. 10 shows the modulus of elasticity, as determined from the dynamic tests, plotted against frequency. In this range, the frequency appears to have no effect upon the dynamic modulus.

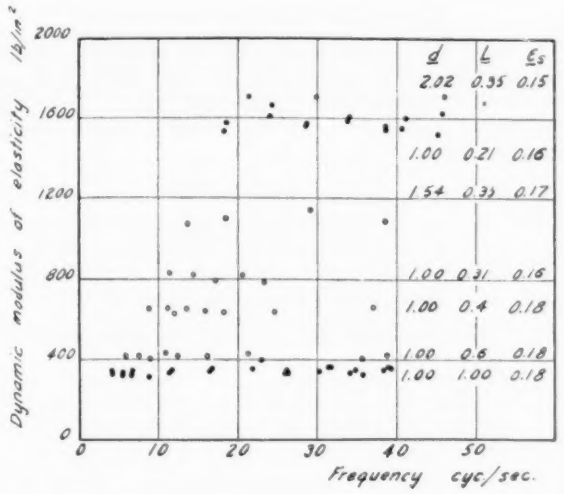

FIG. 10 EFFECT OF FREQUENCY ON DYNAMIC MODULUS OF ELASTICITY

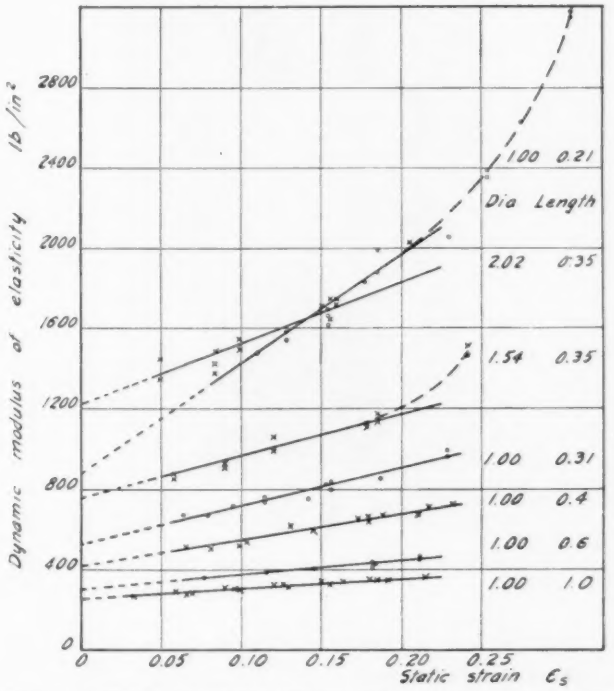

FIG. 11 EFFECT OF STATIC STRAIN ON DYNAMIC MODULUS OF ELASTICITY
(Cylinders in compression.)

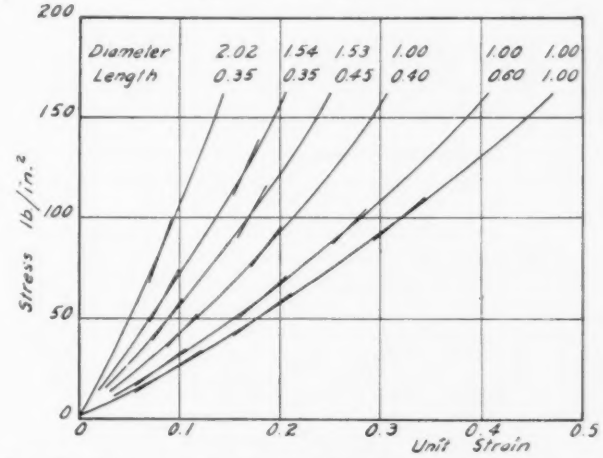

FIG. 13 COMPARISON OF DYNAMIC MODULUS OF ELASTICITY WITH STATIC MODULUS
(Cylinders in compression.)

The effect of static strain upon the dynamic modulus is shown in Fig. 11. The results may be represented as

$$E_{dyn} = E_0 + E_1\epsilon_s$$

for ϵ_s not exceeding 0.2.

Fig. 12 shows the effect of diameter-length ratio upon the factors E_0 and E_1.

Static stress-strain curves for some of the cylinders are shown in Fig. 13, in which the dynamic modulus of elasticity is shown in comparison with the static modulus. The short straight lines represent values of the dynamic modulus. In each case, the line has been drawn to intersect the static curve at the appropriate value of the static strain. It is evident that the dynamic modulus is slightly larger than the static modulus.

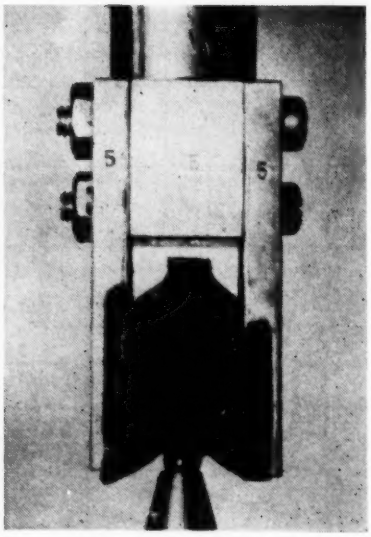

FIG. 15 SHEAR SPECIMEN UNDER STATIC STRAIN OF APPROXIMATELY 1

SHEAR SPECIMENS

Three pairs of specimens were tested in shear. All had the dimensions shown in Fig. 14. Fig. 15 shows a shear specimen under a static strain of approximately 1. There is no extreme end effect such as that seen in the cylinders in Fig. 6. The block D was added after molding and was held in place by means of dowel pins and machine screws. The dimension l was between 0.26 and 0.27 in. after molding. By means of the machine screws, this was brought down to 0.25 in. The latter value was used in calculations.

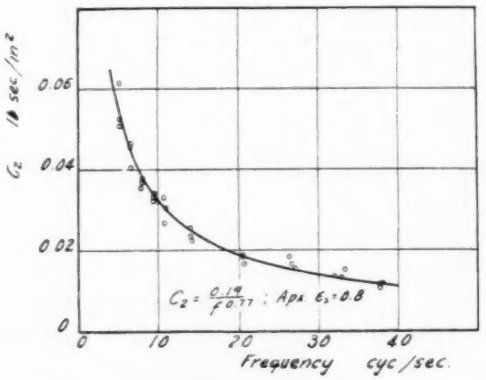

FIG. 16 EFFECT OF FREQUENCY ON DAMPING COEFFICIENT C_2 FOR SHEAR SPECIMENS

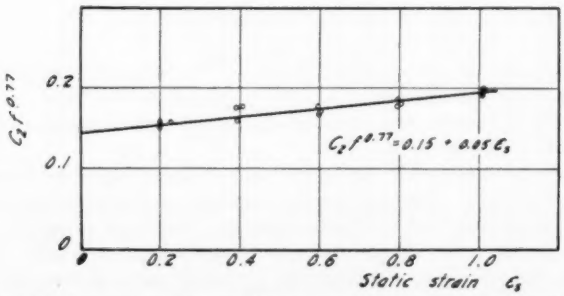

FIG. 17 EFFECT OF STATIC STRAIN ON DAMPING COEFFICIENT C_2 FOR SHEAR SPECIMENS

DAMPING OF CYLINDERS IN SHEAR

The effect of frequency on the damping coefficient C_2 for the shear specimens is shown in Fig. 16, from which it appears that the damping is inversely proportional to $f^{0.77}$.

In Fig. 17, the product $C_2 f^{0.77}$ has been plotted against the static strain ϵ_s

$$C_2 f^{0.77} = 0.15 + 0.05\epsilon_s$$

$$C_2 = \frac{0.15 + 0.05\epsilon_s}{f^{0.77}}$$

DYNAMIC MODULUS OF ELASTICITY

The dynamic modulus of elasticity for the shear specimens is

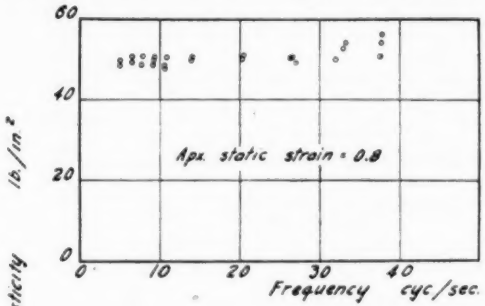

FIG. 18 EFFECT OF FREQUENCY ON DYNAMIC MODULUS OF ELASTICITY FOR SHEAR SPECIMENS

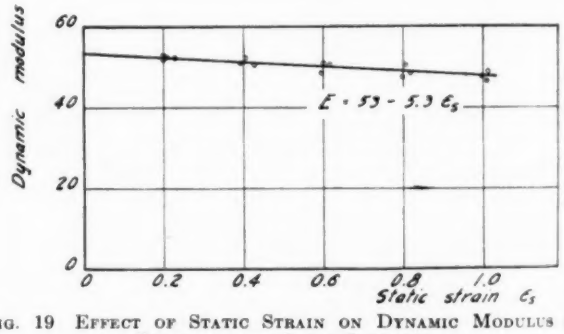

FIG. 19 EFFECT OF STATIC STRAIN ON DYNAMIC MODULUS OF ELASTICITY FOR SHEAR SPECIMENS

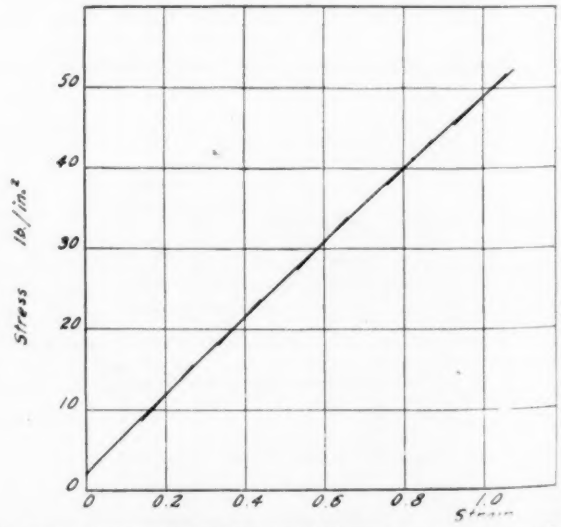

FIG. 20 COMPARISON OF DYNAMIC MODULUS OF ELASTICITY WITH STATIC MODULUS FOR SHEAR SPECIMENS

shown plotted against frequency in Fig. 18. The results indicate that frequency has no effect upon the dynamic modulus.

Fig. 19 shows the effect of static strain on the dynamic modulus. The results may be represented by

$$E_{dyn} = 53 - 5.3\epsilon_s$$

Fig. 20 shows an average static stress-strain curve for the six shear specimens, and a comparison between the dynamic modulus of elasticity and the static modulus. The short straight lines indicate values of the dynamic modulus, each line being drawn to intersect the static curve at the appropriate static strain. The dynamic modulus is slightly higher than the static modulus.

Comparison With Previous Work

In regard to damping, the results stated for cylinders in compression agree fairly well with the conclusions of Kosten[3] and Naunton and Waring.[4] To compare with Roelig,[5] it is necessary to express the results in terms of energy. Since all of Roelig's tests were made on cylinders having a diameter-length ratio of 1, this comparison is based upon results for cylinders of 1 in. diam and 1 in. length. In general

$$\Delta w = \pi C p x_0^2 = 2\pi^2 C f x_0^2$$

where the damping coefficient C is equal to $C_2 \frac{A}{l}$. Term C_2 can be obtained from Fig. 8 as $C_2 = \frac{0.94 + 3.6\epsilon_s}{f^{0.83}}$

$$\Delta w = 2\pi^2(0.94 + 3.6\epsilon_s) f^{0.17} \frac{A}{l} x_0^2 \quad \ldots\ldots\ldots [9]$$

The total energy is

$$W = \frac{1}{2} k x_0^2$$

For one cylinder

$$k = \frac{EA}{l}$$

From Fig. 11

$$E = 240 + 590\epsilon_s$$

so

$$w = \frac{1}{2}(240 + 590\epsilon_s) \frac{A}{l} x_0^2$$

Then

$$\frac{\Delta w}{w} = 4\pi^2 \left(\frac{0.94 + 3.6\,\epsilon_s}{240 + 590\,\epsilon_s}\right) f^{0.17} \ldots\ldots\ldots [10]$$

Equations [9] and [10] are in agreement with the first three conclusions of Roelig,[5] i.e., those in regard to the roles of dynamic load or amplitude, static load, and frequency in affecting the damping. In regard to the effect of volume, Equation [9] may be rewritten as

$$\Delta w = \frac{2\pi^3}{4}(0.94 + 3.6\,\epsilon_s) f^{0.17} x_0^2 l$$

since the diameter is equal to the length. Term Δw varies directly as the length and so increases with volume. Equation [10] shows that $\frac{\Delta w}{w}$ is unaffected by changing the volume.

Equation [9] does not agree with the conclusion of Williams.[6] The energy lost in 1 cycle of stress increases with the frequency.

Results for the dynamic modulus of elasticity agree with the conclusion of Kosten[3] that the dynamic modulus is not affected by change of frequency.

Conclusions

The following conclusions apply to rubber of the stock tested when bonded to steel:

1 For cylinders in compression and specimens in shear, the damping can be expressed in terms of a velocity coefficient. The damping decreases with increase of frequency; it increases with increase of static strain.

2 The dynamic modulus of elasticity is slightly larger than the static modulus and is not affected by change of frequency. It increases with increase of static strain for the cylinders and decreases for the shear specimens.

3 For cylinders in compression, both damping and modulus of elasticity are dependent upon the ratio of diameter to length.

Acknowledgments

The writer takes this opportunity to express his thanks to Prof. J. Ormondroyd, at whose suggestion and under whose direction the project was undertaken.

The specimens used were furnished by the U. S. Rubber Company. Messrs. C. M. Sloman and F. L. Yost were especially helpful in this connection.

Two Problems of Thermal Stress in the Infinite Solid

By N. O. MYKLESTAD,[1] CHICAGO, ILL.

The equations for thermal stress were first developed about 100 years ago by Duhamel (1),[2] who treated the cases of a sphere and a circular cylinder with radial variation of temperature only. As the problem of the cylinder can be considered one of plane strain, it appears that the problem of the sphere (2) is the only three-dimensional one for which a complete solution is available. Borchardt (3) has treated the thermal-stress problem of the sphere for a nonsymmetrical distribution of temperature. Recent developments of the theory (4) have made it possible to complete further solutions. In this paper results are obtained for an infinite solid in which a small internal region, in the form of an ellipsoid of revolution, or a long narrow region, in the form of a semi-infinite circular cylinder, is hotter than the surrounding material. In a finite solid the cylinder may alternately be considered as a blind hole filled with an oversize plug, or a similar shrink fit. The problem of the ellipsoid has some bearing upon the question of the effects of slag inclusion in metals. A discussion by B. P. Haigh (5) deals with the spherical inclusion, whereas, the results of this paper give some indication of the effect of shape variations. The shape of the ellipsoid varies from a flat pancake shape to a thin needle shape, and it is seen that both the pancake-shaped and the needle-shaped inclusions give rise to a higher stress than does the spherical one, for the same temperature variation.

IN THE two problems of this paper, the infinite solid is considered to have the uniform temperature zero outside the hot region, while inside this region the temperature has the constant value of T everywhere. The coefficient of thermal expansion α is considered to be constant, but a variation of α can easily be taken care of by carrying αT through as a single variable quantity. In the case of a small inclusion in the solid, α is the only variable, and T is then merely the uniform temperature change of the solid as a whole.

In Fig. 1 is shown the stress distribution around a hot ellipsoid of revolution in terms of the radii of curvature at the ends of the semiaxes a and c of the generating ellipse, the stresses being those along the extension of the axes. The maximum stress that occurs anywhere in this case is $\frac{E\alpha T}{1-\nu}$ and is normal to the surface of the ellipsoid at a point of minimum radius of curvature of the generating ellipse. This stress occurs only for the case of a pancake-shaped or needle-shaped ellipsoid. For a spherical inclusion, the maximum stress is $\frac{2}{3}\frac{E\alpha T}{1-\nu}$, and is also normal to the surface.

In general the stress in the cold exterior is a maximum at the surface of the ellipsoid of revolution and falls off rather rapidly for points farther out in the exterior. This is in accordance with Saint Venant's principle, and it is seen that, if the minimum dimension of the solid is about 3 times that of the maximum dimension of the inclusion, the solid can for all practical purposes be considered to be infinite.

The results of the second problem are interesting because of the sharp edge around the base of the semi-infinite circular cylinder. In Fig. 2 is shown the normal stresses along radial lines at various distances from the base of the cylinder. The letter n indicates the distance from the base of the cylinder in terms of the radius a.

Fig. 3 shows the normal stresses along lines parallel to the axis of the cylinder and at various distances from it. The letter p indicates the distance from the axis of the cylinder in terms of the radius a.

Fig. 4 shows the shear stress along the plane of the base of the cylinder and along a generator.

From Figs. 2 to 4, it is seen that, for external points, the stresses all drop off rapidly to negligible values in a radial direction and in the axial direction below the base. In the axial di-

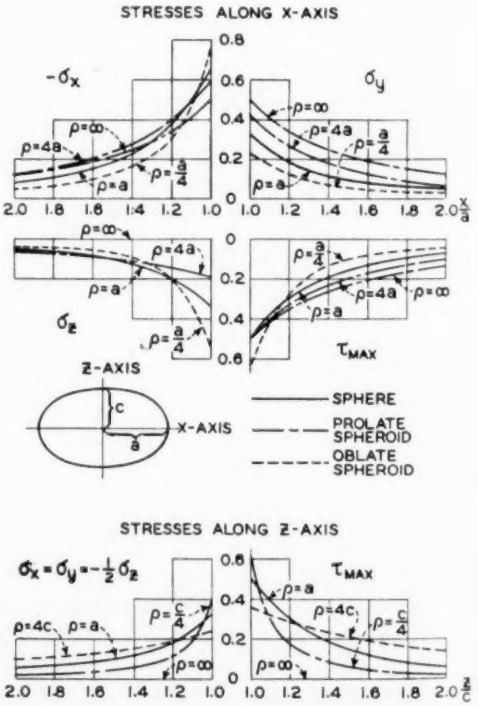

FIG. 1 STRESS DISTRIBUTION AROUND A HOT ELLIPSOID OF REVOLUTION FOR DIFFERENT VALUES OF THE RADIUS OF CURVATURE ρ

(ρ is expressed in terms of the lengths a and c of the semiaxes of the generating ellipse; all values for stress are to be multiplied by $E\alpha T/(1-\nu)$.)

Presented at the National Meeting, of the Applied Mechanics Division, Philadelphia, Pa., June 20–21, 1941, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until October 10, 1942, for publication at a later date. Discussion received after the closing date will be returned.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

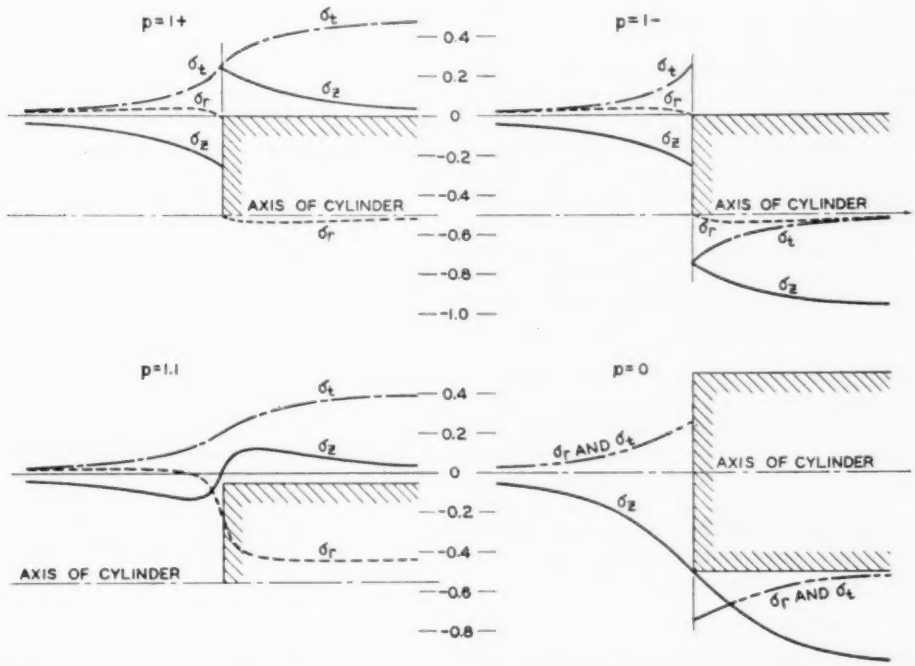

FIG. 3 NORMAL STRESSES, DUE TO A HOT SEMI-INFINITE CIRCULAR CYLINDER, ALONG LINES PARALLEL TO AXIS OF CYLINDER AND AT VARIOUS DISTANCES FROM IT

(p is the distance from the axis of the cylinder in terms of the radius a; all values for stress are to be multiplied by $E\alpha T/[1-\nu]$.)

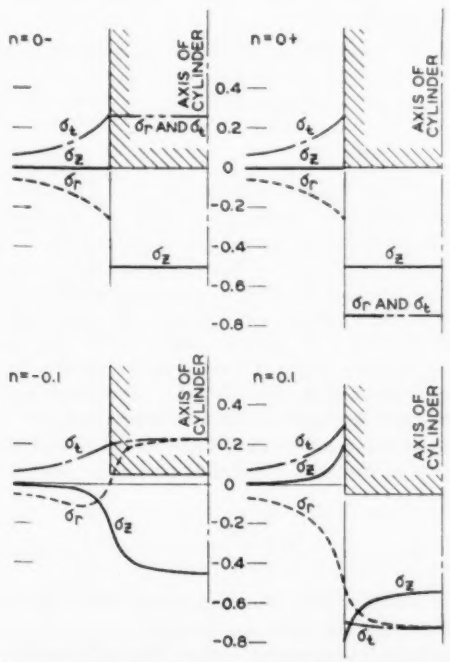

FIG. 2 NORMAL STRESSES, DUE TO A HOT SEMI-INFINITE CIRCULAR CYLINDER, ALONG RADIAL LINES AT VARIOUS DISTANCES FROM BASE OF CYLINDER

(n is the distance from the base of the cylinder in terms of the radius a; all values for stress are to be multiplied by $E\alpha T/[1-\nu]$.)

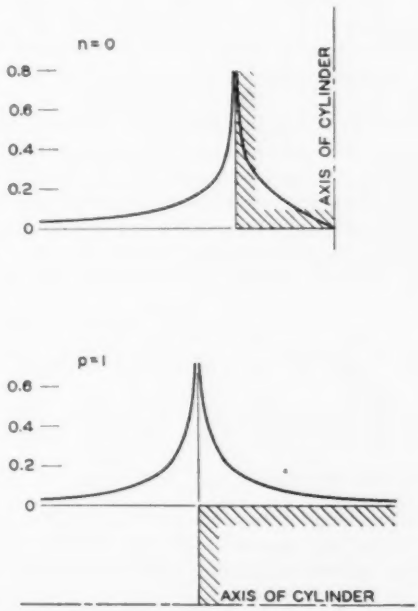

FIG. 4 SHEAR STRESS, DUE TO A HOT SEMI-INFINITE CIRCULAR CYLINDER, ALONG PLANE OF BASE OF CYLINDER AND ALONG A GENERATOR

(All values for stress are to be multiplied by $E\alpha T/[1-\nu]$.)

rection above the base of the cylinder, the radial and tangential stresses rapidly approach the values $-\frac{1}{2}\frac{E\alpha T}{1-\nu}$ and $\frac{1}{2}\frac{E\alpha T}{1-\nu}$, respectively, for points immediately outside the surface, while the axial stress falls off to a negligible value. Inside the cylinder, both the radial and tangential stresses approach the value $-\frac{1}{2}\frac{E\alpha T}{1-\nu}$ while the axial stress approaches the value $-\frac{E\alpha T}{1-\nu}$. To find the stresses in a semi-infinite solid when a blind hole is filled with hotter material, it is only necessary to cut the infinite solid with a plane perpendicular to the axis of the cylinder and at the

proper distance from its base. If a uniform pressure of $\frac{E\alpha T}{1-\nu}$ is applied to the plane of the cut where it is pierced by the cylinder, the same stress distribution is obtained as for the infinite solid. It is now only necessary to remove the local pressure on the surface of the semi-infinite solid to obtain the stress distribution for this case. As the effect of this local pressure is negligible at some distance below the surface, it will only affect slightly the stress distribution around the end of the cylinder. The results from the infinite solid may be used unchanged for the case of the semi-infinite solid when the length of the blind hole is more than twice the diameter. This will then take care of the case of a large solid with a blind hole into which a plug is shrunk or pressed.

From Figs. 2 to 4 it is also seen that at the sharp corner the normal stresses are discontinuous and the shear stress becomes infinite. This implies that the actual shear stress depends upon the degree of rounding of the corner, or that frictional slip will occur in the neighborhood. In the case of an oversize plug, the shear stress will evidently be limited by the degree to which friction can prevent slip between the plug and the hole surfaces. However, a small distance away from the corner the normal stresses will be nearly the same as the values found.

General Theory

When an elastic solid, which is unstressed at a uniform temperature, is given a nonuniform temperature $T(x, y, z)$ that is not linear in x, y, z, the natural expansion of a volume element will be restricted by the surrounding material and a state of stress will ensue. The difference between the actual strain and the natural expansion αT of a volume element is related to the stress through Hooke's law; α being the linear coefficient of thermal expansion. For simplicity, it is assumed that the original uniform temperature is zero. This makes no difference in the theory because a uniform change of temperature creates no stress in an isotropic solid. It is also assumed that the elastic constants of the material do not vary considerably over the temperature range in question, although a variation of α with temperature can be taken care of by carrying αT through as a single variable quantity.

Let u, v, w be the total displacements in the x, y, z directions, respectively, then the components of normal and shear strain are

$$\left.\begin{aligned} &\epsilon_x = \frac{\partial u}{\partial x}, \quad \epsilon_y = \frac{\partial v}{\partial y}, \quad \epsilon_z = \frac{\partial w}{\partial z}, \\ &\gamma_{xy} = \frac{\partial u}{\partial y} + \frac{\partial v}{\partial x}, \quad \gamma_{xz} = \frac{\partial u}{\partial z} + \frac{\partial w}{\partial x}, \quad \gamma_{yz} = \frac{\partial v}{\partial z} + \frac{\partial w}{\partial y} \end{aligned}\right\} \quad \ldots\ldots [a]$$

Also, the volume expansion $e = \epsilon_x + \epsilon_y + \epsilon_z$.

As a uniform change of temperature of a small volume element does not create any angular distortion of the element, the shear stresses will be unaffected by the term αT or, $\tau_{xy} = G\gamma_{xy}$, etc., where $G = \frac{E}{2(1+\nu)}$ is the modulus of elasticity in shear, E the modulus of elasticity in tension and compression (assumed equal), and ν Poisson's ratio. The normal stresses, however, are determined by the following equation

$$\sigma_x = \frac{E}{1+\nu}\left[\frac{\nu}{1-2\nu}\, e + \epsilon_x - \frac{1+\nu}{1-2\nu}\,\alpha T\right] \ldots\ldots [1]$$

and two more by interchanging x with y and z.

The three equations of equilibrium take the form

$$(\lambda + G)\frac{\partial e}{\partial x} + G\nabla^2 u - \frac{\alpha E}{1-2\nu}\frac{\partial T}{\partial x} = 0$$

and two more by interchanging x with y and z, and u with v and w. Also

$$\lambda = \frac{\nu E}{(1+\nu)(1-2\nu)} \quad \text{and} \quad \nabla^2 = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2}$$

Substituting for λ and G these equations become

$$\frac{\partial e}{\partial x} + (1-2\nu)\nabla^2 u = 2\alpha(1+\nu)\frac{\partial T}{\partial x} \ldots\ldots [2]$$

etc. Equations [1] and [2] are the fundamental equations of the theory.

In order to obtain particular integrals of Equation [2], a function φ is introduced and defined in such a manner that

$$\frac{\partial \varphi}{\partial x} = u, \quad \frac{\partial \varphi}{\partial y} = v, \quad \frac{\partial \varphi}{\partial z} = w$$

By means of Equations [a], the strains can be expressed in terms of the function φ as follows

$$\epsilon_x = \frac{\partial^3 \varphi}{\partial x^3}, \quad \epsilon_y = \frac{\partial^3 \varphi}{\partial y^3}, \quad \epsilon_z = \frac{\partial^3 \varphi}{\partial z^3} \ldots\ldots [b]$$

$$e = \nabla^2 \varphi \ldots\ldots [c]$$

$$\gamma_{xy} = 2\frac{\partial^3 \varphi}{\partial x \partial y}, \quad \gamma_{xz} = 2\frac{\partial^3 \varphi}{\partial x \partial z}, \quad \gamma_{yz} = 2\frac{\partial^3 \varphi}{\partial y \partial z} \ldots\ldots [d]$$

Equation [2] can now be written

$$\frac{\partial}{\partial x}\left[(1-\nu)\nabla^2 \varphi - (1+\nu)\alpha T\right] = 0$$

etc. It is seen that Equation [2] is all satisfied when

$$\nabla^2 \varphi = \frac{1+\nu}{1-\nu}\,\alpha T \ldots\ldots [3]$$

Evidently any function φ, which satisfies Equation [3], provides a particular integral of Equation [2]. The state of stress and strain represented by this function φ will ordinarily require certain surface forces at the boundary of the solid. These surface forces can be determined from the conditions of equilibrium at the boundary and the stresses there, expressed in terms of φ. To complete the problem, it is necessary to apply equal and opposite forces to the surface of the solid and determine the stresses from these, as in an ordinary (isothermal) boundary-value problem. By superposition, the complete stress resulting from unequal heating of the solid can then be determined.

The function φ is called the "displacement potential."

By means of Equation [3], Equation [1] can now be written in the form

$$\sigma_x = 2G\left[\frac{\partial^2 \varphi}{\partial x^2} - \frac{1+\nu}{1-\nu}\,\alpha T\right] \ldots\ldots [1a]$$

etc. It is seen that only the second derivatives of φ are necessary to determine the stress components.

Equation [3] is of the same form as Poisson's equation $\nabla^2 V = -4\pi\rho$, and a particular integral is given by the Newtonian potential of a distribution of matter of density ρ per unit of volume

$$V = \int\int\int \frac{\rho}{r}\, d\xi d\eta d\zeta$$

In this equation V is the potential at the point (x, y, z), the co-ordinates ξ, η, ζ refer to a point in the solid where the density is ρ, and the integration is throughout the solid. The distance r, between the points (x, y, z) and (ξ, η, ζ), is given by the equa-

tion $r = \sqrt{(x-\xi)^2 + (y-\eta)^2 + (z-\zeta)^2}$. Putting $\frac{1+\nu}{1-\nu}\alpha T = -4\pi\rho$ the following equation for φ is obtained

$$\varphi(x, y, z) = -\frac{1+\nu}{1-\nu}\frac{\alpha}{4\pi}\int\int\int \frac{T(\xi, \eta, \zeta)}{r}\, d\xi d\eta d\zeta \quad [4]$$

When the inequalities of temperature are of a purely local nature in an infinite solid, $T = 0$ outside the hot part of the solid, φ will vanish at infinity because ξ, η, ζ are bounded, and consequently r goes to infinity when the point (x, y, z) goes to infinity. As $T(\xi, \eta, \zeta)$ is independent of (x, y, z), differentiation under the integral sign shows that the displacements will vanish as r^{-2} and the stresses as r^{-3}, when the point (x, y, z) goes to infinity. As this satisfies the boundary conditions for an infinite solid, the solution in this case is completely represented by Equation [4].

Discontinuous Temperature Distribution

The general Equation [2] implies the existence of the first derivatives of the temperature, and the validity of any solution at a surface S of temperature discontinuity therefore requires examination. By means of potential theory it is easily shown, however, that the solution of Equation [4] is also valid when T has surface discontinuities, and that any component of normal stress, acting on an element of area normal to, and at, the surface of discontinuity is discontinuous by an amount $\frac{E\alpha}{1-\nu}(T_i - T_e)$, while the component of normal stress acting on an element of the surface S is continuous. T_i is the temperature immediately inside the surface S and T_e is the temperature immediately outside S.

All these conclusions remain true even when the solid has finite boundaries. The boundary forces, corresponding to Equation [4], are to be canceled by superposing an isothermal stress distribution having equal and opposite boundary values. But any distribution of boundary forces, whether continuous or not, produces a stress that is continuous in the interior. The discontinuity of stress due to a temperature discontinuity remains unaffected, although the absolute values of the stresses on either side of S will in general be modified.

It is not necessary that S lie entirely within the boundary. It may cut it in one or more curves. When it does, the complementary surface forces on the boundary are discontinuous at these curves. When it does not, these forces are continuous all over the boundary.

Solution to Problem 1

Stresses set up in an "isotropic infinite solid" when part of it, bounded by an "ellipsoid of revolution," is at a higher uniform temperature than the rest of the solid.

Let the ellipsoid be formed by rotating an ellipse $\frac{x^2}{a^2} + \frac{z^2}{c^2} = 1$, with semiaxes a and c, about the z axis. The equation for the ellipsoid of revolution then becomes $\frac{x^2+y^2}{a^2} + \frac{z^2}{c^2} = 1$.

It is shown under "General Theory" that the stresses are found immediately from the potential of an ellipsoid of uniform mass density $\rho = -\frac{1+\nu}{1-\nu}\frac{\alpha T}{4\pi}$. The constant temperature of the ellipsoid is considered equal to T and in the cold exterior equal to zero.

The normal stresses are given by Equation [1a], and as $T = 0$ for the cold exterior, the stresses in this part of the infinite solid will be

$$\sigma_x = \frac{E}{1+\nu}\frac{\partial^2\varphi}{\partial x^2} \quad [5]$$

Both for external and internal points the shear stresses are

$$\tau_{xy} = \frac{E}{1+\nu}\frac{\partial^2\varphi}{\partial x \partial y} \quad [5a]$$

etc.

First consider the case of an "oblate spheroid" $a > c$, for which the potential (6) is

$$V = \frac{\pi\rho a^2 c}{a^2 - c^2}\left[\left(2\sqrt{a^2-c^2} - \frac{x^2+y^2-2z^2}{\sqrt{a^2-c^2}}\right)\sin^{-1}\sqrt{\frac{a^2-c^2}{a^2+\kappa}} + \frac{\sqrt{c^2+\kappa}}{a^2+\kappa}(x^2+y^2) - \frac{2z^2}{\sqrt{c^2+\kappa}}\right] \quad [6]$$

and κ is determined as being the positive root in the equation

$$\frac{x^2+y^2}{a^2+\kappa} + \frac{z^2}{c^2+\kappa} = 1 \quad [7]$$

By introducing the eccentricity $e = \frac{\sqrt{a^2-c^2}}{a}$, c can be eliminated. Also κ can be found by means of Equation [7]. Differentiation of Equation [6] then yields the following expressions for the stresses

$$\left.\begin{aligned}
\sigma_x &= \frac{E\alpha T}{1-\nu}\frac{a\sqrt{1-e^2}}{2e^2}\left[\frac{1}{ae}\sin^{-1}\frac{ae}{\sqrt{a^2+\kappa}} - \frac{\sqrt{c^2+\kappa}}{a^2+\kappa} - \frac{e^2a^2x}{(a^2+\kappa)^2\sqrt{c^2+\kappa}}\frac{\partial\kappa}{\partial x}\right] \\
\sigma_y &= \frac{E\alpha T}{1-\nu}\frac{a\sqrt{1-e^2}}{2e^2}\left[\frac{1}{ae}\sin^{-1}\frac{ae}{\sqrt{a^2+\kappa}} - \frac{\sqrt{c^2+\kappa}}{a^2+\kappa} - \frac{e^2a^2y}{(a^2+\kappa)^2\sqrt{c^2+\kappa}}\frac{\partial\kappa}{\partial y}\right] \\
\sigma_z &= \frac{E\alpha T}{1-\nu}\frac{a\sqrt{1-e^2}}{2e^2}\left[\frac{2}{\sqrt{c^2+\kappa}} - \frac{2}{ae}\sin^{-1}\frac{ae}{\sqrt{a^2+\kappa}} - \frac{e^2a^2z}{(a^2+\kappa)(c^2+\kappa)^{3/2}}\frac{\partial\kappa}{\partial z}\right]
\end{aligned}\right\} \quad [8]$$

and

$$\tau_{xy} = -\frac{E\alpha T}{1-\nu}\frac{a^3\sqrt{1-e^2}}{2(a^2+\kappa)^2\sqrt{c^2+\kappa}}\left[1 + \frac{r^2-e^2a^2}{\sqrt{(r^2-e^2a^2)^2+4e^2a^2z^2}}\right]xy$$

$$\tau_{xz} = -\frac{E\alpha T}{1-\nu}\frac{a^3\sqrt{1-e^2}}{2(a^2+\kappa)^2\sqrt{c^2+\kappa}}\left[1 + \frac{r^2+e^2a^2}{\sqrt{(r^2-e^2a^2)^2+4e^2a^2z^2}}\right]xz$$

$$\tau_{yz} = -\frac{E\alpha T}{1-\nu}\frac{a^3\sqrt{1-e^2}}{2(a^2+\kappa)^2\sqrt{c^2+\kappa}}\left[1 + \frac{r^2+e^2a^2}{\sqrt{(r^2-e^2a^2)^2+4e^2a^2z^2}}\right]yz$$

In the foregoing expressions $r^2 = x^2 + y^2 + z^2$ and

$$a^2 + \kappa = \frac{1}{2}\left[r^2 + e^2a^2 + \sqrt{(r^2-e^2a^2)^2 + 4e^2a^2z^2}\right]$$

$$c^2 + \kappa = \frac{1}{2}\left[r^2 - e^2a^2 + \sqrt{(r^2-e^2a^2)^2 + 4e^2a^2z^2}\right]$$

$$\frac{\partial \kappa}{\partial x} = \left[1 + \frac{r^2 - e^2a^2}{\sqrt{(r^2 - e^2a^2)^2 + 4e^2a^2z^2}}\right] x$$

$$\frac{\partial \kappa}{\partial y} = \left[1 + \frac{r^2 - e^2a^2}{\sqrt{(r^2 - e^2a^2)^2 + 4e^2a^2z^2}}\right] y$$

$$\frac{\partial \kappa}{\partial z} = \left[1 + \frac{r^2 + e^2a^2}{\sqrt{(r^2 - e^2a^2)^2 + 4e^2a^2z^2}}\right] z$$

Now consider the case of a "prolate spheroid" $c > a$, for which the potential is

$$V = \frac{\pi\rho a^2 c}{c^2 - a^2}\left[\left(2\sqrt{c^2 - a^2} + \frac{x^2 + y^2 - 2z^2}{\sqrt{c^2 - a^2}}\right)\sinh^{-1}\sqrt{\frac{c^2 - a^2}{a^2 + \kappa}} - \frac{\sqrt{c^2 + \kappa}}{a^2 + \kappa}(x^2 + y^2) + \frac{2z^2}{\sqrt{c^2 + \kappa}}\right]$$

This time a will be eliminated by means of the eccentricity $e = \frac{\sqrt{c^2 - a^2}}{c}$, and the formulas for stress will be

$$\left.\begin{aligned}
\sigma_x &= \frac{E\alpha T}{1 - \nu}\frac{c(1 - e^2)}{2e^2}\left[\frac{\sqrt{c^2 + \kappa}}{a^2 + \kappa} - \frac{1}{ec}\sinh^{-1}\frac{ec}{\sqrt{a^2 + \kappa}} - \frac{e^2c^2x}{(a^2 + \kappa)^2\sqrt{c^2 + \kappa}}\frac{\partial \kappa}{\partial x}\right] \\
\sigma_y &= \frac{E\alpha T}{1 - \nu}\frac{c(1 - e^2)}{2e^2}\left[\frac{\sqrt{c^2 + \kappa}}{a^2 + \kappa} - \frac{1}{ec}\sinh^{-1}\frac{ec}{\sqrt{a^2 + \kappa}} - \frac{e^2c^2y}{(a^2 + \kappa)^2\sqrt{c^2 + \kappa}}\frac{\partial \kappa}{\partial y}\right] \\
\sigma_z &= \frac{E\alpha T}{1 - \nu}\frac{c(1 - e^2)}{2e^2}\left[\frac{2}{ec}\sinh^{-1}\frac{ec}{\sqrt{a^2 + \kappa}} - \frac{2}{\sqrt{c^2 + \kappa}} - \frac{e^2c^2z}{(a^2 + \kappa)(c^2 + \kappa)^{3/2}}\frac{\partial \kappa}{\partial z}\right]
\end{aligned}\right\} \quad [9]$$

and

$$\tau_{xy} = -\frac{E\alpha T}{1 - \nu}\frac{c^3(1 - e^2)}{2(a^2 + \kappa)^2\sqrt{c^2 + \kappa}}\left[1 + \frac{r^2 + e^2c^2}{\sqrt{(r^2 + e^2c^2)^2 - 4e^2c^2z^2}}\right] xy$$

$$\tau_{xz} = -\frac{E\alpha T}{1 - \nu}\frac{c^3(1 - e^2)}{2(a^2 + \kappa)^2\sqrt{c^2 + \kappa}}\left[1 + \frac{r^2 - e^2c^2}{\sqrt{(r^2 + e^2c^2)^2 - 4e^2c^2z^2}}\right] xz$$

$$\tau_{yz} = -\frac{E\alpha T}{1 - \nu}\frac{c^3(1 - e^2)}{2(a^2 + \kappa)^2\sqrt{c^2 + \kappa}}\left[1 + \frac{r^2 - e^2c^2}{\sqrt{(r^2 + e^2c^2)^2 - 4e^2c^2z^2}}\right] yz$$

In the foregoing expressions put

$$a^2 + \kappa = \frac{1}{2}\left[r^2 - e^2c^2 + \sqrt{(r^2 + e^2c^2)^2 - 4e^2c^2z^2}\right]$$

$$c^2 + \kappa = \frac{1}{2}\left[r^2 + e^2c^2 + \sqrt{(r^2 + e^2c^2)^2 - 4e^2c^2z^2}\right]$$

$$\frac{\partial \kappa}{\partial x} = \left[1 + \frac{r^2 + e^2c^2}{\sqrt{(r^2 + e^2c^2)^2 - 4e^2c^2z^2}}\right] x$$

$$\frac{\partial \kappa}{\partial y} = \left[1 + \frac{r^2 + e^2c^2}{\sqrt{(r^2 + e^2c^2)^2 - 4e^2c^2z^2}}\right] y$$

$$\frac{\partial \kappa}{\partial z} = \left[1 + \frac{r^2 - e^2c^2}{\sqrt{(r^2 + e^2c^2)^2 - 4e^2c^2z^2}}\right] z$$

All stresses thus considered are for the cold exterior. The most interesting stresses in the cold exterior are those along the axis of the ellipsoid and along a line, through the centroid, perpendicular to the axis. These stresses, along the z and x axes, respectively, have been calculated for different radii of curvature ρ at the ends of the semiaxes of the ellipse $\frac{x^2}{a^2} + \frac{z^2}{c^2} = 1$. The results are plotted in Fig. 1.

Stresses in the Interior of the Hot Ellipsoid

From the form of the potential of an ellipsoid at interior points, it is easily seen that the shear stresses in the interior are all zero and that the normal stresses can be derived from Equations [8] and [9] by putting $\kappa = \frac{\partial \kappa}{\partial x} = \frac{\partial \kappa}{\partial y} = \frac{\partial \kappa}{\partial z} = 0$ and subtracting $\frac{E\alpha T}{1 - \nu}$ according to Equation [1a].

For an "oblate spheroid" these stresses become

$$\sigma_x = \sigma_y = -\frac{E\alpha T}{1 - \nu}\left[1 + \left(\sqrt{1 - e^2} - \frac{1}{e}\sin^{-1}e\right)\frac{\sqrt{1 - e^2}}{2e^2}\right]$$

$$\sigma_z = -\frac{E\alpha T}{1 - \nu}\left[1 + \left(\frac{1}{e}\sin^{-1}e - \frac{1}{\sqrt{1 - e^2}}\right)\frac{\sqrt{1 - e^2}}{e^2}\right]$$

and for a "prolate spheroid"

$$\sigma_x = \sigma_y = -\frac{E\alpha T}{1 - \nu}\left[1 + \left(\frac{1}{e}\sinh^{-1}\frac{e}{\sqrt{1 - e^2}} - \frac{1}{1 - e^2}\right)\frac{1 - e^2}{2e^2}\right]$$

$$\sigma_z = -\frac{E\alpha T}{1 - \nu}\left[1 + \left(1 - \frac{1}{e}\sinh^{-1}\frac{e}{\sqrt{1 - e^2}}\right)\frac{1 - e^2}{e^2}\right]$$

It is interesting to note that the normal stresses in the interior are all constant and dependent only upon the shape of the ellipsoid, as exemplified by the eccentricity e.

Inside a hot sphere it is easily seen that the normal stresses are all equal to $-\frac{2}{3}\frac{E\alpha T}{1 - \nu}$, while inside a pancake-shaped ellipsoid the stresses are found to be $\sigma_x = \sigma_y = -\frac{E\alpha T}{1 - \nu}$ and $\sigma_z = 0$. Inside a needle-shaped ellipsoid, the normal stresses are $\sigma_x = \sigma_y = -\frac{1}{2}\frac{E\alpha T}{1 - \nu}$ and $\sigma_z = -\frac{E\alpha T}{1 - \nu}$.

Solution to Problem 2

Stresses set up in an "isotropic infinite solid" when part of it, bounded by a "semi-infinite circular cylinder," is at a higher uniform temperature than the rest of the solid.

As far as the author has been able to ascertain, the potential of a semi-infinite circular cylinder is not known. However, it is the second derivatives of this potential which are required in order to find the stress, and the determination of these second derivatives constitutes the major part of this problem.

The first derivatives of the potential of a homogenous body can be found in terms of a surface potential by means of Gauss's

theorem. Then the attraction at a point P of a solid body of any form, when resolved parallel to any straight line (taken as the axis of x), is given as

$$\frac{\partial V}{\partial x} = \rho \int \frac{\cos\theta}{r}\, d\omega$$

where ρ is the constant density of the body, r the distance from P to any element $d\omega$ of the area of the surface, and θ is the angle the normal at $d\omega$, drawn inward, makes with the positive direction of x. This is true both for external and internal points.

The co-ordinate system is now located in such a manner that the origin is at the center of the base circle and the positive z axis forms the axis of the cylinder. The base of the semi-infinite circular cylinder, then, lies in the xy plane. The attraction in the z direction is readily seen to be the potential of the surface of the base of the cylinder with a mass density ρ per unit of area.

The potential (7) of a circular disk of radius a and mass density ρ per unit of area is

$$\frac{\partial V}{\partial z} = 2\rho a^2 \int_{\lambda_1}^{\infty} \sqrt{1 - \frac{r^2}{a^2+\psi} - \frac{z^2}{\psi}}\, \frac{d\psi}{(a^2+\psi)\sqrt{\psi}} \quad \ldots [10]$$

where the disk lies in the xy plane with the center at the origin. The quantity $r^2 = x^2 + y^2$, and λ_1 is the algebraically larger (positive) root of the equation

$$\frac{r^2}{a^2+\lambda} + \frac{z^2}{\lambda} = 1 \quad \ldots [11]$$

the smaller (negative) root of which is λ_2. Solving Eq. [11] gives

$$\left.\begin{aligned} \lambda_1 &= \frac{1}{2}\left[r^2 + z^2 - a^2 + \sqrt{(r^2+z^2-a^2)^2 + 4a^2z^2}\right] \\ \lambda_2 &= \frac{1}{2}\left[r^2 + z^2 - a^2 - \sqrt{(r^2+z^2-a^2)^2 + 4a^2z^2}\right] \end{aligned}\right\} \quad \ldots [12]$$

Differentiating Equation [10] and putting $\rho = -\dfrac{1+\nu}{1-\nu}\dfrac{\alpha T}{4\pi}$ yields

$$\left.\begin{aligned} \frac{\partial^2\varphi}{\partial x \partial z} &= \frac{1+\nu}{1-\nu}\frac{\alpha T}{2\pi} a^2 x \int_{\lambda_1}^{\infty} \frac{d\psi}{(\psi+a^2)\sqrt{(\psi+a^2)(\psi-\lambda_1)(\psi-\lambda_2)}} \\ \frac{\partial^2\varphi}{\partial y \partial z} &= \frac{1+\nu}{1-\nu}\frac{\alpha T}{2\pi} a^2 y \int_{\lambda_1}^{\infty} \frac{d\psi}{(\psi+a^2)\sqrt{(\psi+a^2)(\psi-\lambda_1)(\psi-\lambda_2)}} \\ \frac{\partial^2\varphi}{\partial z^2} &= \frac{1+\nu}{1-\nu}\frac{\alpha T}{2\pi} a^2 z \int_{\lambda_1}^{\infty} \frac{d\psi}{\psi\sqrt{(\psi+a^2)(\psi-\lambda_1)(\psi-\lambda_2)}} \end{aligned}\right\} \quad \ldots [13]$$

Evaluation of the elliptic integrals (8) in Equation [13] and substitution into the formulas for stress gives

$$\left.\begin{aligned} \tau_{xz} &= \frac{E\alpha T}{1-\nu}\frac{a^2 x}{\pi}\frac{K-E}{(a^2+\lambda_2)\sqrt{a^2+\lambda_1}} \\ \tau_{yz} &= \frac{E\alpha T}{1-\nu}\frac{a^2 y}{\pi}\frac{K-E}{(a^2+\lambda_2)\sqrt{a^2+\lambda_1}} \end{aligned}\right\} \quad \ldots [14]$$

everywhere in the infinite solid, and

$$\sigma_z = \frac{E\alpha T}{1-\nu}\frac{z}{\pi\sqrt{a^2+\lambda_1}}\left\{\frac{dn(v,k')}{k'^2 sn(v,k') cn(v,k')}\left[KE(v,k') + \left(\frac{\pi}{2} - KE'\right)\frac{v}{K'}\right] - K\right\} \quad \ldots [15]$$

for exterior points only. For interior points the normal stress in the direction of the axis of the cylinder is obtained from Equation [15] by subtracting $\dfrac{E\alpha T}{1-\nu}$, according to Equation [1a].

The functions entering into the foregoing formulas for stress are defined in the following manner

$$k = \sqrt{\frac{\lambda_2}{a^2+\lambda_1}} \quad \ldots [16]$$

which quantity is always smaller than 1, as λ_2 is smaller than λ_1. Also k is always taken as positive.

By means of Equation [12], k may be written

$$k = \frac{2ra}{r^2+z^2+a^2+\sqrt{(r^2+z^2-a^2)^2+4a^2z^2}} \quad \ldots [16a]$$

$$k = \frac{r^2+z^2+a^2-\sqrt{(r^2+z^2-a^2)^2+4a^2z^2}}{2ra} \quad \ldots [16b]$$

K and E are the complete elliptic integrals of the first and second kind, respectively, and K' and E' are the same complete elliptic integrals with modulus $k' = \sqrt{1-k^2}$.

Also

$$v = \int_0^{\varphi'} \frac{d\varphi}{\sqrt{1-k'^2\sin^2\varphi}}$$

$$E(v,k') = \int_0^{\varphi'} \sqrt{1-k'^2\sin^2\varphi}\, d\varphi$$

$$sn(v,k') = \sin\varphi'$$

$$cn(v,k') = \cos\varphi' = \sqrt{1-sn^2(v,k')}$$

$$dn(v,k') = \sqrt{1-k'^2\, sn^2(v,k')}$$

φ' is determined (9) by the equation $dn(v,k') = \dfrac{\sqrt{a^2+\lambda_2}}{a}$ and from this all the other elliptic functions, entering into Equation [15], can be found.

From Equation [16a], it is easily seen that k is the same for $z = +m$ as for $z = -m$, where m is any positive number, which then also holds for the elliptic functions and integrals. It follows immediately that the two shear stresses, Equations [14], are symmetrical with respect to the xy plane and that the normal stress σ_z, according to Equation [15] has equal, but opposite, stress for $z = +m$ and $z = -m$.

For the purpose of numerical calculation, the equations for stress can be greatly simplified by means of Equations [12] and [16a and b]; also by putting $r = pa$ and $z = na$, where a is the radius of the cylinder. By introducing cylindrical co-ordinates r, θ, z the two shear stresses, Equations [14], can immediately be reduced to one. Putting $x = r = pa$, $y = 0$, and $z = na$ gives

$$\left.\begin{aligned} \tau_{rz} &= \frac{E\alpha T}{1-\nu}\frac{1}{\pi}\sqrt{\frac{1}{pk}}\,(K-E) \\ \tau_{r\theta} &= 0 \end{aligned}\right\} \quad \ldots [17]$$

By expressing the elliptic functions entering into Equation [15] in terms of p and k and eliminating n by means (10) of Equation [16b] the normal stress σ_z can finally be written as

$$\sigma_s = \pm \frac{E\alpha T}{1-\nu}\left[\frac{K}{\pi}\left(E(v,k') - \frac{v}{K'}E' - \sqrt{\frac{(1-pk)(p-k)}{p}}\right) + \frac{1}{2}\frac{v}{K'}\right] \quad [18]$$

where the plus sign is to be used for positive z and the minus sign for negative z. Equation [18] is good for all external points except the z axis ($p = 0$). To obtain σ_s for internal points, it is only necessary to subtract $\frac{E\alpha T}{1-\nu}$ from the right-hand side of Equation [18].

Along the z axis it can be shown (11) that

$$\sigma_z = -\frac{1}{2}\frac{E\alpha T}{1-\nu}\left[1 + \frac{n}{\sqrt{1+n^2}}\right] \quad [19]$$

where n is positive when z is positive and negative when z is negative, and Equation [19] is good for both external and internal points.

Radial and Tangential Stresses

The radial and tangential stresses can also be found by means of Gauss's theorem. The attraction of the semi-infinite cylinder in the radial direction is the same as the attraction in the x direction for a point in the xz plane, and is equal to the potential of a cylindrical shell with a surface distribution of matter of $-\rho \cos\theta$, θ being the angle between the xz plane and a plane through the axis of the cylinder. As only the second derivatives are required in order to find the stress, it is not necessary to find the potential of the cylindrical shell, but only its attraction in the x direction upon a point in the xz plane. This is done by splitting the surface up into semi-infinite rods of width $a \cdot d\theta$ and mass per unit of length $\rho \cos\theta a d\theta$, and making use of the well-known formulas for the attractions of a semi-infinite rod of uniform mass density (12). This gives

$$\frac{\partial^2 V}{\partial r^2} = a\rho \int_0^{2\pi} \frac{r - a\cos\theta}{r^2 + a^2 - 2ar\cos\theta}\left(1 + \frac{z}{\sqrt{r^2+z^2+a^2-2ar\cos\theta}}\right)\cos\theta d\theta \quad [20]$$

where $r^2 = x^2 + y^2$.

To find the second derivative in the tangential direction of the potential of the solid cylinder, it is only necessary to turn the cylindrical shell 90 deg about its axis and find its attraction in the y direction upon a point in the xz plane. This gives

$$\frac{\partial^2 V}{\partial t^2} = a^2\rho \int_0^{2\pi} \frac{\sin^2\theta}{r^2 + a^2 - 2ar\cos\theta}\left(1 + \frac{z}{\sqrt{r^2+z^2+a^2-2ar\cos\theta}}\right)d\theta \quad [21]$$

Now put $z = na$ and, for r larger than a put $r = pa$, but for r smaller than a put $a = p'r$. Then Equations [20] and [21] will reduce to the form

$$\left.\begin{aligned}\frac{\partial^2 V}{\partial r^2} &= \rho \int_0^{2\pi} \frac{\rho\cos\theta - \cos^2\theta}{p^2 + 1 - 2p\cos\theta}\left(1 + \frac{n}{\sqrt{p^2+n^2+1-2p\cos\theta}}\right)d\theta \\ \frac{\partial^2 V}{\partial t^2} &= -\rho \int_0^{2\pi} \frac{1-\cos^2\theta}{p^2+1-2p\cos\theta}\left(1 + \frac{n}{\sqrt{p^2+n^2+1-2p\cos\theta}}\right)d\theta\end{aligned}\right\} \quad [22]$$

when r is larger than a, and to the form

$$\left.\begin{aligned}\frac{\partial^2 V}{\partial r^2} &= p'\rho \int_0^{2\pi} \frac{\cos\theta - p'\cos^2\theta}{p'^2 + 1 - 2p'\cos\theta}\left(1 + \frac{np'}{\sqrt{p'^2 + n^2p'^2 + 1 - 2p'\cos\theta}}\right)d\theta \\ \frac{\partial^2 V}{\partial t^2} &= -p'^2\rho \int_0^{2\pi} \frac{1-\cos^2\theta}{p'^2+1-2p'\cos\theta}\left(1 + \frac{np'}{\sqrt{p'^2+n^2p'^2+1-2p'\cos\theta}}\right)d\theta\end{aligned}\right\} \quad [23]$$

when r is smaller than a.

Integrating Equations [22] and [23] (13) the following results are obtained

$$\sigma_r = -\frac{E\alpha T}{1-\nu}\frac{1}{4\pi p^2}\left\{\pi + \frac{n}{\sqrt{(p+1)^2+n^2}}\left[\{(p+1)^2 + n^2\}(K-E) - (p^2+2p-1)K\right] \mp (p^2+1)\left[KE(v,k') - \frac{KE'v}{K'} + \frac{\pi v}{2K'}\right]\right\} \quad [24]$$

$$\sigma_t = \frac{E\alpha T}{1-\nu}\frac{1}{4\pi p^2}\left\{\pi + \frac{n}{\sqrt{(p+1)^2+n^2}}\left[\{(p+1)^2 + n^2\}(K-E) + (p-1)^2K\right] \mp (p^2-1)\left[KE(v,k') - \frac{KE'v}{K'} + \frac{\pi v}{2K'}\right]\right\} \quad [25]$$

for r larger than a and, by putting $p = \frac{1}{p'}$

$$\sigma_r = \frac{E\alpha T}{1-\nu}\frac{1}{4\pi}\left\{\pi - \frac{n}{p^2\sqrt{(p+1)^2+n^2}}\left[\{(p+1)^2 + n^2\}(K-E) - (p^2+2p-1)K\right] - \frac{p^2+1}{p^2}\left[KE(v,k') - \frac{KE'v}{K'} + \frac{\pi v}{2K'}\right]\right\} \quad [24a]$$

$$\sigma_t = \frac{E\alpha T}{1-\nu}\frac{1}{4\pi}\left\{\pi + \frac{n}{p^2\sqrt{(p+1)^2+n^2}}\left[\{(p+1)^2 + n^2\}(K-E) + (p-1)^2K\right] - \frac{p^2-1}{p^2}\left[KE(v,k') - \frac{KE'v}{K'} + \frac{\pi v}{2K'}\right]\right\} \quad [25a]$$

for r smaller than a. These are the stresses at exterior points. For interior points the stresses are

$$\sigma_r = -\frac{E\alpha T}{1-\nu}\frac{1}{4\pi}\left\{3\pi + \frac{n}{p^2\sqrt{(p+1)^2+n^2}}\left[\{(p+1)^2 + n^2\}(K-E) - (p^2+2p-1)K\right] - \frac{p^2+1}{p^2}\left[KE(v,k') - \frac{KE'v}{K'} + \frac{\pi v}{2K'}\right]\right\} \quad [24b]$$

$$\sigma = -\frac{E\alpha T}{1-\nu}\frac{1}{4\pi}\left\{3\pi - \frac{n}{p^2\sqrt{(p+1)^2+n^2}}\left[\{(p+1)^2+n^2\}(K-E)+(p-1)^2K\right] - \frac{p^2-1}{p^2}\left[KE(v,k') - \frac{KE'v}{K'} + \frac{\pi v}{2K'}\right]\right\} \quad [25b]$$

In Equations [24] to [25*b*], the elliptic integrals are determined by

$$k^2 = \frac{4p}{(p+1)^2+n^2}$$

$$k'^2 = 1-k^2 = \frac{(p-1)^2+n^2}{(p+1)^2+n^2}$$

$$sn^2(v,k') = \sin^2\varphi' = \frac{n^2}{(p-1)^2+n^2}$$

v and $E(v, k')$ are defined in the same manner as before in the expression for axial stress.

The stress formulas outlined do not hold when p equals zero, or for points along the z axis. In this case, however, it is quite simple to find the attractions of the cylindrical shell at points along its axis (14). This gives

$$\sigma_r = \sigma_t = \frac{1}{4}\frac{E\alpha T}{1-\nu}\left(1+\frac{n}{\sqrt{1+n^2}}\right) \quad [26]$$

for external points (n negative), and

$$\sigma_r = \sigma_t = -\frac{1}{4}\frac{E\alpha T}{1-\nu}\left(3-\frac{n}{\sqrt{1+n^2}}\right) \quad [26a]$$

for internal points (n positive).

From symmetry it is immediately seen that $\tau_{r\theta} = 0$.

The most interesting stresses are those near the end of the cylinder, and particularly at the sharp circular edge. The stresses have been calculated for different values of n and p, and the results are plotted in Figs. 2 to 4.

ACKNOWLEDGMENTS

The author wishes to express his gratitude to Dr. J. N. Goodier, professor of mechanics of engineering, Cornell University, for having suggested the problems of this paper and for invaluable aid in their solution. He also wishes to thank Dr. H. Poritsky, engineering general department, General Electric Company, for a valuable suggestion in the solution of the second problem.

Discussion

Solution of Problems of Elasticity by the Framework Method[1]

DOUGLAS MCHENRY.[2] The need for a simple versatile method of finding the numerical solutions of particular problems in elasticity has become rather pressing, and the author's description of the framework method may well serve to open an important new field in structural-design methods. To the writer, this need has recently become urgent. By coincidence, his attack upon the problem followed lines identical with those pursued by the author and resulted in what the writer has called a "lattice analogy." The term analogy is used for obvious reasons although, as shown by the author, the plate and the lattice may (as a limiting condition) become identical, in so far as concerns the solution of stress problems. The framework or lattice method was found to be best adapted to two-dimensional problems in plane stress, using the simple cross-braced square frame. For this type of problem, it offers about all that might be desired in the way of versatility and simplicity of computation. The restriction upon the value of Poisson's ratio is a matter of very slight practical importance. Problems involving any type of body forces may be handled readily, as may the formally intractable problem of stress due to temperature differentials. Only minor complications are introduced, if the section cuts through two or more materials of different densities, or different elastic properties (provided that μ is kept at $^1/_3$). Even reinforced concrete may be simulated by the lattice with an apparent degree of success and with little added difficulty in computation.

It is of particular interest to note that, in the braced framework, the state of stress or strain at each joint is completely specified in terms of three direct forces or three elongations, a specification which is in many respects more logical than the conventional one involving shearing stress and strain.[3] In solving a framework, the rather inconvenient concept of shear may be omitted completely.

The amount of labor required by a beginner in the method to reach a satisfactory solution of a practical problem is apt to be discouraging. However, the writer has solved several problems by this method (first, of course, those for which rigorous solutions were also available) and has found that familiarity with the method will suggest numerous devices to effect great savings in time and labor. The cost of a solution is in most cases probably comparable to that of a photoelastic analysis, and many problems can be handled satisfactorily by either method. However, for certain problems, one or the other of the two methods may possess a distinct superiority.

The method of solving the highly indeterminate framework may be selected to suit the preference of the computer, but some systematic method of successive approximation appears to be called for. The writer recommends that, in the plane-stress problem, the solution be carried out entirely in terms of displacements. The successive release of joints along a loaded boundary will yield a first approximation to the boundary displacements; then, with the boundary fixed in its new position, the interior displacements, resulting from the successive release of interior joints, may be computed without regard to the forces causing these displacements. The unbalanced forces may be computed as a final step to investigate the accuracy of the solution. Considering, for example, the four-frame assembly of the author's Fig. 7, if the horizontal and vertical components of displacement are designated h and v, with the joints lettered a, b, c, ... h, with a at the top center, then with given displacements assigned to the eight surrounding joints, we have for the corresponding displacement of the center joint, o

$$h_o = \frac{1}{12}\,(h_b + v_b + 4h_c + h_d - v_d + h_f + v_f + 4h_g + h_h - v_h)$$

$$v_o = \frac{1}{12}\,(4v_a + h_b + v_b - h_d + v_d + 4v_e + h_f + v_f - h_h + v_h)$$

The corresponding equations for other assemblies, either with or without boundary loads or body forces, may be easily derived.

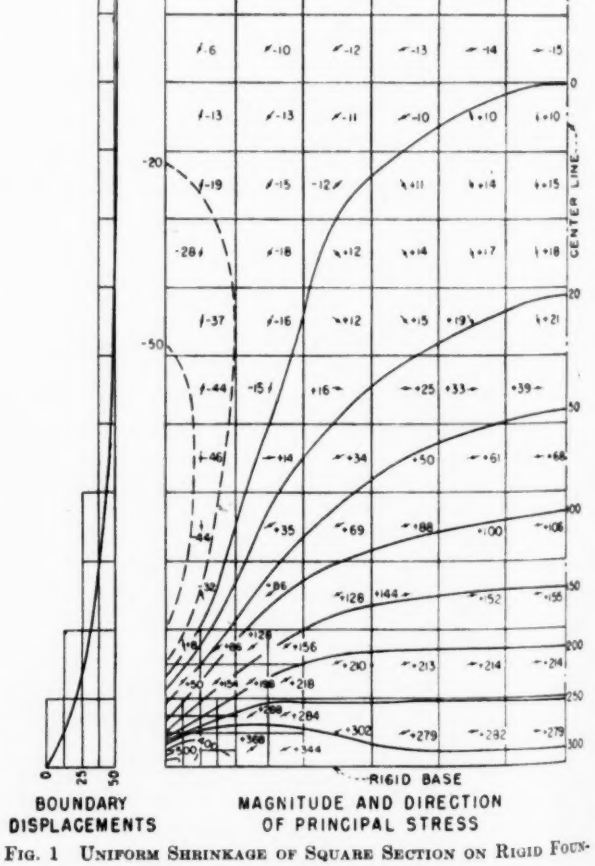

FIG. 1 UNIFORM SHRINKAGE OF SQUARE SECTION ON RIGID FOUNDATION

(Magnitude of numerically greatest stress shown by contours, direction by dashes. For uniform shrinkage of 100 millionths inch per inch, displacements are in millionths of base length and stresses are in pounds per square inch if $E = 3 \times 10^6$.)

[1] By A. Hrennikoff, published in the December, 1941, issue of the JOURNAL OF APPLIED MECHANICS, Trans. A.S.M.E., vol. 63, p. A-169.

[2] Engineer, U. S. Bureau of Reclamation, Denver, Colo.

[3] This point is discussed in "A New Specifying Method for Stress and Strain in an Elastic Solid," by Lord Kelvin, Proceedings of the Royal Society of Edinburgh, vol. 24, 1901–1902, pp. 97–101.

At each step, total displacements (rather than increments) are computed directly. Thus the shape of the deformed structure is continuously visualized, a condition which aids in introducing estimated displacements to speed the convergence of the process. Such estimates can and should be used freely; for the final result must be correct within some specified reasonable error regardless of the course by which it is reached.

The relaxation concept as described is a convenient one in that it assigns an easily visualized physical meaning to the adjustment process. However, it should be pointed out that mathematically the process is simply an iterative one, corresponding closely to the well-known method of solving Laplace's equation for given boundary conditions by averaging, at each point, assigned values at four equidistant surrounding points.

A typical solution of considerable practical interest is shown by Fig. 1 of this discussion, representing the stresses and the boundary displacements produced by uniform shrinkage of a square section on a rigid foundation. The framework method is particularly well adapted to this type of problem, for solutions from given displacements converge more rapidly than do those from given forces.

The possibility of constructing framework models for the solution of two-dimensional problems should receive consideration. The scheme appears to be entirely feasible provided the models are prestressed in tension to avoid buckling of the members under compressive stress.

Author's Closure

The similarity of the method of "lattice analogy," used by the discusser, with the author's framework method is very interesting, and the type of the lattice pattern, employed by the discusser, seems identical with the author's simple square framework. This type is suitable for solving all plane-stress problems in which the value of Poisson's ratio is $1/3$, as well as the problems involving other values of μ, in which the boundary conditions are represented by some known forces on the periphery of the framework. However, if some body forces, temperature distortions, or some known boundary displacements enter the question, the use of the simple square pattern is theoretically incorrect. This remark applies to the problem of shrinkage of a wall on a rigid foundation, illustrated in Fig. 1 of the discussion, since the value of Poisson's ratio of concrete is considerably below $1/3$. The use of the general type of square framework, suitable for any value of μ, would have obviated this error. This objection should not, however, detract from giving the discusser due credit for solving the problem of such complexity. The same criticism would apply also to photoelastic solutions of the problems just referred to, and in this fact there lies a distinct advantage of the framework method over the photoelastic method.

In analyzing framework stresses, the author has found the distribution procedure outlined in the paper to be the most convenient method of solution, especially in conjunction with the principles of symmetry and antisymmetry. It is true that the proficiency of such work depends a great deal upon the experience of the computer, and the results are likely to be discouraging for a beginner; but, once the technique of the distribution is mastered and the short cuts are well understood, some very formidable framework analyses may be accomplished expeditiously. Thus, in one of the problems solved by the author, an 8 by 12 simple square framework, acted upon by unsymmetrical forces, was analyzed and checked in approximately 200 hr, in which period of time the unbalanced joint forces were reduced from several thousand pounds to fractions of a pound. An equivalent solution by joint displacements, along the lines which are suggested by the discusser, would involve 231 simultaneous equations, and the labor required for it would be entirely out of the question.

The writer joins the discusser in recommending construction of a model of the square framework with $\mu = 1/3$. However, a model of the general type of square framework would seem to be impossible.

The Technical Cohesive Strength of Metals[1]

R. G. Sturm.[2] It is a real contribution to human progress when a new concept, such as technical cohesive strength of metals, or any other arbitrarily defined concept, is set forth for study and verification. Such a concept has been presented by W. Kuntze, who has shown considerable experimental evidence to establish trends in this "property" which he has introduced. It is a further contribution when such a new concept is critically examined and compared with the facts of human experience, in so far as such facts are obtainable. This the author has done very carefully. Inasmuch as Kuntze's work was written in German, it would have added considerable value to the author's paper if he had, at the beginning, outlined just what phenomena in the behavior of metals during the production of metal parts or in the service of these parts are indicated by the technical cohesive strength of metals.

The writer is not as familiar with Kuntze's work as he would like to be, but perhaps the author could give an answer to two specific questions for the benefit of practical physicists and engineers. Does the technical cohesive strength help to explain internal fractures sometimes encountered in overdrawn wire? Does the technical cohesive strength have anything to do with longitudinal splitting of brittle materials subjected to axial compression?

Apparently most investigators have found that in determining the technical cohesive strength, as in determining tensile strength, the speed of deformation is frequently a significant factor. For example, a recent test indicates that a bar held a sustained load of 50 per cent of the short-time tensile strength for $10^1/_2$ years and then failed. The elongation of the bar at the end of this long-time test was about 9 times the elongation obtained in the short-time test. It took approximately 8 years for the specimen to exhibit any indication of failure. This left $2^1/_2$ years for the failing process to continue. Actual stress based on the reduced area at fracture was 63 per cent of the nominal short-time tensile strength of the material. The question occurs: Did the material fracture when the actual stress reached the technical cohesive strength? If so, is this the technical cohesive strength of the original material in the bar or the material that has been elongated an amount equal to 9 times the elongation obtainable in a short-time test?

The writer would like further to supplement the author's examination of the technical cohesive strength obtained by notched specimens. It is true that, at the base of a notch of predetermined size and shape in a round specimen, the calculated stress concentration for an elastic material would be the same regardless of the over-all dimensions of the material, as long as the geometry of the notch and specimen is not changed. However, it is not possible to change grain size as we change specimen size. A sharp notch has a radius comparable to the grain size of metals. As soon as plastic action occurs at the base of a notch, the distribution of stresses in the vicinity of the notch is obviously changed, and the extent of this change in stress distribution would

[1] By D. J. McAdam, Jr., published in the December, 1941, issue of the Journal of Applied Mechanics, Trans. A.S.M.E., vol. 63, p. A-155.

[2] New Kensington, Pa. Mem. A.S.M.E.

be expected to vary with the amount of local deformation which takes place. Therefore at the center of the specimen there exists an entirely different phenomenon than exists immediately adjacent to the base of the notch. In view of the uncertainty in the determination of the technical cohesive strength, the author is quite justified in raising the question as to whether or not it is the technical cohesive strength or some other value which governs fracture of metals.

Author's Closure

Mr. Sturm has made a very welcome contribution to the discussion. His description of the results of a very lengthy test of a specimen under steady load is very interesting. The influence of the factors involved in this experiment will be discussed by the author in a paper now in preparation. Mr. Sturm's reference to the initial stress concentration and the deformation gradient in the cross section apparently indicates that he agrees with the views on this subject, expressed in the paper. The final sentence in his discussion, however, indicates a misunderstanding. The views expressed in the paper are in entire accord with the idea that fracture is determined by the technical cohesive strength, in the absence of an important stress gradient (premature fracture). The technical cohesion limit, however, has been shown to depend on the combination of principal stresses.

An Extension of the Sand-Heap Analogy in Plastic Torsion Applicable to Cross Sections Having One or More Holes[1]

R. E. Bruckner.[2] The method given in this paper for determining the torsional strength of irregularly shaped sections is so simple and readily understandable as to be of great value to the average designing engineer who is apt to be a bit rusty in his mathematics. The writer tried to check the author's Equation [1]

$$M = 2\frac{k}{m}V$$

as applied to a solid circular shaft against the conventional formula, such as that given by Timoshenko.[3]

Assume a shaft 5 in. diam of solid cross section with a value for the surface shear stress

$$S_s \text{ or } k = 5000 \text{ psi}$$

Calculated by the conventional method, the allowable torque load would be

$$(\pi/16)5^3 \times 5000 = 122{,}000 \text{ lb-in.}$$

Calculated by the author's Equation [1], and assuming various values for the slope m, the torque load becomes 164,000 lb-in., which is roughly 33 per cent larger than the allowable load calculated by the conventional formula, which considers the polar moment of inertia of the cross section. The present writer has been unable to resolve this discrepancy.

It is of interest to note that the ratio V/m is a constant for circular sections. Does this hold true for all sections? If so, this fact would be of importance.

A. Nádai.[4] Problems of finding the distributions of stress in perfectly plastic bodies, with cross sections connected in multiple, have some remarkable properties not encountered, for example, in the corresponding elastic states of stress. If a small disturbance is produced along one of the boundary curves of the area for which the plastic solution is sought, observation and also the theory show that it will propagate itself into the interior along definite curves. In the case of the plastic torsion of a bar, these curves are the normals of the boundary curve of the cross section of the twisted bar, i.e., the projections of the straight generatrices of the surface of constant slope which can be constructed above the boundary curves on the plane of the cross section.

If a small notch is made in the boundary line of the cross section, a small quantity of sand will run off from the surface of constant slope along the straight generatrix passing through the notch, but the shape of the sand heap otherwise will not be disturbed except along this narrow strip.

If the cross section has one or more holes in its interior, each point of the inner boundary curves must be considered as a center of a disturbance. The result of these disturbances is that new surfaces of constant slope will be generated around each hole and the external boundary line. The author is to be commended on having clarified the conditions to be met when the cross-sectional area has one or several holes, and of having determined the heights required of the planes in which the bases of these new surfaces of equal constant slope have to be assumed. An interesting fact becomes evident, namely, that the heights of the bases are independent of each other.

The rule which determines the heights is also extremely simple. The plane above a hole parallel to the base plane of the cross section must be raised to that height at which the generatrix, which marks the shortest distance between the external boundary curve and the boundary of the hole, intersects this latter curve. Therefore, the first thing to do is to draw the normals to the external boundary curve of the cross section and to find the ones having the shortest lengths measured between the external boundary curve and the nearest boundary of a hole. The heights at which these "shortest" generatrices reach the surfaces of the holes determine the inner edges of the surfaces of constant slope starting from the holes. The base planes above the holes have to be adjusted at such heights that the corresponding "inner" surfaces of constant slope do not cut away anything from the "shortest" generatrices.

This has been illustrated by three examples, shown by their contour lines in Fig. 1 (*a*), (*b*), and (*c*).[5] Following the schemes indicated by the author, brass models[6] were also made of the first two, as shown in Fig. 2 of this discussion. After correct adjustment of the tubes marking the inner edges, the sand heaps, Figs. 3 and 4, were produced. Since in these two models only circles and straight lines are used in the external boundary and in the curves determining the holes, the surfaces of constant slope which correspond to them are either straight circular vertical cones or planes, all having the same slope. The projections of the inner ridges along which the surfaces intersect each other

[1] By M. A. Sadowsky, published in the December, 1941, issue of the Journal of Applied Mechanics, Trans. A.S.M.E., vol. 63, p. A-166.

[4] Consulting Mechanical Engineer, Westinghouse Research Laboratories, East Pittsburgh, Pa. Mem. A.S.M.E.

[5] With particular reference to Fig. 1. (*a*), subsequent to the presentation of this discussion at the National Meeting of the Applied Mechanics Division, at Philadelphia, on June 20, 1941, Prof. N. M. Newmark of the University of Illinois advised the writer that a figure representing the stress surface of a round bar in torsion, having an eccentric circular hole, already had been published by H. M. Westergaard. ("Graphostatics of Stress Functions," by H. M. Westergaard, Trans. A.S.M.E., vol. 56, 1934, pp. 141–149, Fig. 3.) In that paper, the rule of using the shortest distance between the inner and outer boundaries was also mentioned.

[6] The models were constructed by S. W. Hagerling.

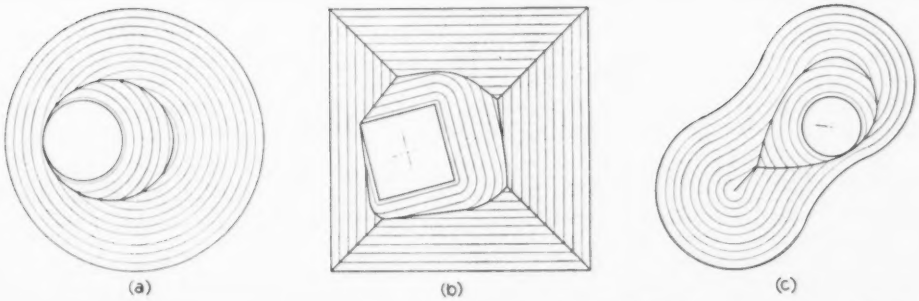

FIG. 1 PLASTIC TORSION; STRESS SURFACES FOR BARS HAVING CROSS SECTIONS WITH HOLES

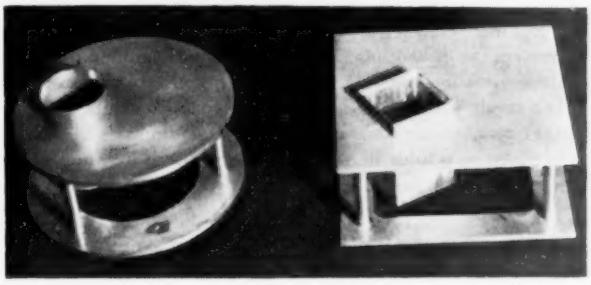

FIG. 2 FRAMES FOR PRODUCING SAND HILLS

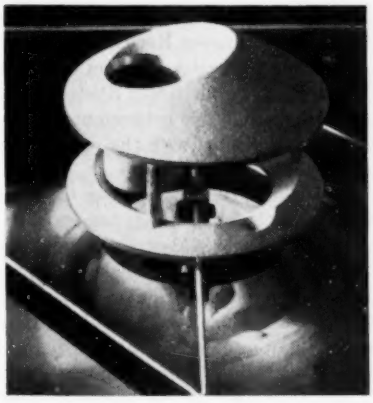

FIG. 3 STRESS SURFACE FOR CIRCULAR CROSS SECTION HAVING A CIRCULAR HOLE

are either portions of straight lines or else arcs of ordinary parabolas (intersection of a cone with a plane having the same slope as the generatrices of the cone).

The case of the plastic torsion of a bar with a circular cross section, having an eccentric circular hole, Figs. 1 (*a*) and 3, leads to a stress surface consisting of two equal circular cones. A "ridge"

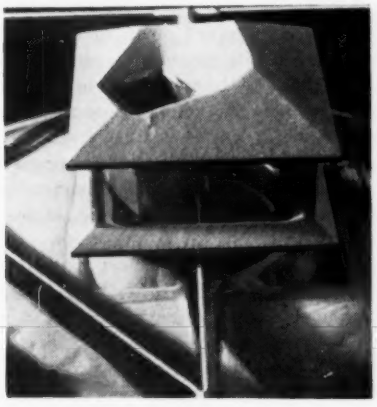

FIG. 4 STRESS SURFACE FOR SQUARE CROSS SECTION HAVING A SQUARE HOLE

appears in this case which has degenerated to a true ellipse both in space and in its projection on the base plane shown in Fig. 1 (*a*). It is perhaps of interest to note that, in the case of a square cross section with a square hole, the inner surface consists of four planes and of four inverted cones the apexes of which are situated in the corners of the holes. The sand heap around three of the re-entrant corners consists of such cones, as can indeed be verified by comparing the shape shown in Fig. 4.

AUTHOR'S CLOSURE

Mr. Bruckner rightly observes that the torsional moment, M, is smaller in elastic ("conventional") torsion than in plastic torsion. For a circular cross section the ratio of the corresponding torsional moments is 3:4 which confirms Mr. Bruckner's 33 per cent. The ratio V/m is constant for any shape of the cross section.

The author wishes to express his particular appreciation to Dr. Nádai and Mr. Hagerling for the experimental realization of the models and for the photographs.

Book Reviews

Track Stress Research

TRACK STRESS RESEARCH PROGRESS REPORT, November, 1935—November, 1938, Government of India Railway Department. By W. E. Gelson and E. A. Blackwood, Investigating Officers. East Indian Railway Press, Calcutta, India, 1939. Cardboard, 8½ × 13 in., Vol. 1, 113 pp., 74 figs.; Vol. 2 (Appendices), ix and 309 pp. of curves and figures. Each volume Rs. 10 or 16s.

REVIEWED BY B. F. LANGER[1]

THIS publication is a report of an investigation which was undertaken to find the answers to some specific problems regarding the adequacy of the track used in Indian railways. It is of interest to readers in this country because it is a good report on what was apparently a well-conducted study. The quantitative results must be considered with due regard for the differences between American and British track construction. The majority of tests were made on Bull head rails of less than 100 lb weight.

The subjects studied included the effect of speed, the adequacy of rail joints, the stability of track in the ballast (forces necessary to produce permanent distortion), the stresses in rails, and the forces produced by hunting movements of locomotives.

In the study of speed effect, the rail was considered in the conventional way as a beam on an elastic foundation, and the differential equations were solved for both static and moving loads. The theory was found to agree quite well with the measured stresses at low speed. At higher speeds the measured vertical deflections agreed fairly well with the theoretical values, but the bending stresses were found to be higher than those predicted except when the rails and fastenings were in excellent condition. Empirical formulas are given for the effect of speed, based on maximum test values for various types of vehicles.

On the subject of rail joints, it was found that most of those tested were inadequate. A joint always produces a discontinuity in track stiffness which can be at best only partly compensated by extra support at the joint. Therefore joints have an important effect on stresses produced by dynamic loads. It is the opinion of the investigators that a large part of the impact effect is due to inadequacy of the joints.

The problem of measuring the lateral force necessary to produce permanent distortion of the track has always been a difficult one because a moving load can displace the track in the ballast more easily than a static load. The investigators made static tests but also supplemented them with dynamic tests in which two locomotives were lashed together and run on parallel tracks. Lateral force was obtained by means of springs which pushed the locomotives apart. On the basis of 4 mm permanent distortion as the criterion of failure, the critical loads were found to vary from 12.2 to 14.9 English tons. The tests showed that the lateral strength of track depends chiefly on the tie spacing and the value of the grip the ties take in the ballast. The type of rail was found to have no appreciable effect within the limits of the experiments.

The investigators were well aware of the fact that failure of the rail itself is not generally produced by the primary bending stress but by secondary stresses associated with distortions of the rail cross section. Photoelastic tests were made in which the distortion measured in a full rail was reproduced in a two-dimensional xylonite model. These tests showed the importance of the fillet under the head as a possible point of failure under the action of eccentric vertical load.

Flange forces were measured on the locomotives during operation by means of tubular struts arranged so as to take the lateral forces between the flanges and the locomotive frame. The compression of the struts was measured with electromagnetic strain gages. Other instruments used included optical deflectometers for recording vertical rail deflection, Baldwin-Southwark inductor telemeters for measuring rail stress, and various simple but adequate devices for applying and measuring effects of static loads.

As a result of the tests the authors were able to draw many important conclusions, some of which are mentioned here, as well as to make up a table of safe speeds for various locomotives and cars on various types of track.

Thermodynamics

THERMODYNAMICS. By Joseph H. Keenan. John Wiley and Sons, Inc., New York, N. Y., 1941. Cloth, 6 × 9 in., xi and 499 pp., 221 figs., $4.50.

REVIEWED BY MILTON C. STUART[2]

IT IS gratifying that Professor Keenan, who has long since attained pre-eminence in the development of tables of numerical values of thermodynamic properties of fluids, should now present an exposition of the relationships between properties and the heat and work quantities associated with the processes of science and engineering.

In a broad sense, this book accomplishes three things. It presents those basic principles of thermodynamics which are common to all processes, it illustrates the engineering applications in an unusually effective manner, and it breaks down the boundaries which have heretofore seemed to isolate into compartments the thermodynamics of mechanical engineering, physics, and chemistry. The present-day mechanical engineer needs to be able to apply in the expanding fields of engineering some parts of thermodynamics formerly held sacred as chemical thermodynamics. On the other hand, the chemical engineer may profit from a knowledge of the applications of the science which were exclusively within the province of the mechanical engineer.

A few of the headings of the twenty-six chapters reveal the scope of the book: The First Law of Thermodynamics, Properties of a Pure Substance, the Second Law of Thermodynamics, Reversibility, Availability, the Reciprocating Steam Engine, Steam Turbine, Heat Engine Cycles, Mixtures of Gases and Vapors, Refrigeration, Heat and Power From Combustion, the Flow of Fluids in Ducts, the Relation Between Pressure, Volume, and Temperature, Thermodynamic Temperature and the International Scale of Temperature, Equilibrium of a Pure Substance Supersaturated Vapor and Superheated Liquid, Chemical Equilibrium, and the Chemical Potential.

A brief survey of the author's definitions of the basic thermodynamic concepts will be of interest. Heat and work are both emphasized as being transient forms of energy. Heat is defined as energy "which transfers from one system to a second system at lower temperature, by virtue of the temperature difference . . ."

[2] Professor of Mechanical Engineering, Lehigh University, Bethlehem, Pa. Mem. A.S.M.E.

Work is interpreted in a generalized fashion as energy flowing "from a system (and to another) during a given operation if the sole effect external to the system could be the rise of a weight." Of the various possible avenues of approach to the internal-energy concept, the author chooses that which defines the internal-energy change of a system as the integral of the heat and work during a change of state of the system. The fact that this integral is zero for a cyclic process is the First Law, and leads to the important conclusion that the internal-energy change between any two states is independent of the type of process by which the system passes between two states. Internal energy thus joins the family of properties of a system.

The author rejects entirely the molecular view of internal energy because "it is generally true that the exposition of thermodynamics is simplified by ignoring the molecule." It must be pointed out, however, that the molecule is not ignored on page 366, where is explained the method of experimental determination of the internal energy of water vapor by examination of band spectra. There need be no quarrel here between different schools because all realize that thermodynamics is, as stated in the first sentence of Professor Keenan's book, only "the science of the relationship between heat, work, and the properties of systems." Numerical values of properties must be found by empirical methods borrowed from other sciences.

It has been said that there are at least fifty statements of the Second Law of thermodynamics. The author paraphrases Planck's statement, "It is impossible to construct an engine which will work in a complete cycle and produce no effect except to raise a weight and exchange heat with a single reservoir." As a consequence of this law, entropy is defined as the integral of dQ/T for any reversible path between two state points.

The temperature function is derived in a most satisfactory manner without fuss or feathers in chapter 21. The most violent purist could find no fault in the author's definition of other thermodynamic functions, such as enthalpy and the specific heats.

It is impossible to mention here the many features which are original or are treated in a unique manner. Among those which appeal to this reviewer are: The presentation of two categories of internal energy, one bearing the symbol U, which is a function of thermodynamic properties, the other bearing the symbol E, which includes U and all other forms of stored energy; the approach to the steady flow process through a more general treatment of an "open system;" the analysis of the steam turbine based on zero angles of approach and departure of the steam through the blading, and on the momentum equation; the emphasis which is placed on availability, in particular the availability studies of the ammonia-absorption cycle, the internal-combustion process, and the steam-power cycle; the use of the b function and the β function; the treatment of the metastable states of supersaturated vapor and superheated liquid; the explanation of the methods for determining numerical values for the properties of fluids; the criteria of equilibrium and the application of equilibrium principles to a pure substance; the use of the Fanno line and the Rayleigh line in flow analysis; and the study of chemical equilibrium and chemical potential, which will serve as an introduction to the mighty work of Gibbs.

An examination of the auxiliary features of the book reveals a list of symbols tabulated for ready reference at the end of the chapter. However, no reference is made to units. This omission may be a point of strength, because the formulas stand in any consistent system of units. At the end of each chapter is a list of ten to twenty problems and questions. Answers are not provided, but the data are well stated and instructions for proceeding are clear. A few examples are solved and explained, but the book has been written with a precision which requires a strong mathematical background for the student.

Professor Keenan has adopted a style which is characterized by comprehensiveness, clearness of exposition, and the avoidance of verbosity. He states in the opening sentence of the preface that "the object of this book is to give a simple and rigorous exposition of the First and Second Laws of thermodynamics." It is the opinion of this reviewer that this object has been attained.

Dynamics of Straight Railroad Track

BEITRAG ZUR DYNAMIK DES GERADEN EISENBAHNGELEISES (Contribution to the Dynamics of Straight Railroad Track). Dissertation completed at the University of Göttingen, Germany, by the reviewer in 1933. 28 pages, 15 × 22 cm., $2 per copy from author.

BY BERTRAM K. HOVEY[3]

BY substituting a substitution in the form of the sum of two exponential terms in a well-known, partial-differential equation of the fourth order for a bar on a continuous, massless, elastic foundation, the general form of the steady-state solution for the motion of the bar when acted upon by a sinusoidally varying force moving with uniform linear velocity along the bar was obtained. The solution consists of two components having damped sine-wave envelopes which disappear at infinity. One of these components proceeds and the other follows the moving load. All the arbitrary constants in the general solution were evaluated by boundary conditions which the two components were required to meet at the moving load. Since the differential equation is linear, the solution for any type of load consisting of a constant term plus harmonic terms can be obtained by superposition.

For the case of a single, sinusoidal load moving with uniform, linear velocity, an auxiliary relationship gives the critical limit for ideal railroad track in the form of a functional relationship between frequency and linear velocity. A calculation for a constant load plus a superimposed sinusoidal load with values selected to correspond to heavy loading of actual railroad track showed that the critical limit, which is lower for a combination of a constant plus a sinusoidal load than for a sinusoidal load alone, was exceeded for ideal railroad track. Evidently, when the loading of actual railroad track is such that this theoretical, critical limit is exceeded, factors not taken into account in the ideal solution limit the amplitude of motion of the track.

Elastic Energy Theory

ELASTIC ENERGY THEORY. By J. A. Van Den Broek, Ph.D., Professor of Engineering Mechanics, University of Michigan. Second edition. John Wiley & Sons, Inc., New York, N. Y., 1942. Cloth, 6 × 9 in., xvii and 298 pp., 95 figs., $4.50.

REVIEWED BY J. N. GOODIER[4]

IN Strength of Materials, and Theory of Structures, deformations are analyzed from (at least) two distinct points of view. One considers the deformations of the infinitesimal elements and builds them up by geometrical considerations into the over-all deflections required. The other avoids the geometry, or most of it, by considering the work-energy relations and deriving deflections from them. In Castigliano's theorem the strain energy is differentiated with respect to a force to give the deflection component in its direction at the point of action. A theorem equivalent to Castigliano's (any distinction between the two being merely in the order of the integration over the elements of the

[4] Professor in Charge, Department of Mechanics of Engineering, Sibley School of Mechanical Engineering, Cornell University, Ithaca, N. Y. Mem. A.S.M.E.

structure, and the differentiation with respect to the force) is obtained by considering a fictitious force applied where the deflection is to be found and writing down an equation of work which involves the required deflection. This is often called the method of virtual work.

The present book is based on an enthusiasm for this method, as superior to other available methods—notably that of the "elastic curve" in which the deflection curves of bars are separately determined and reconciled geometrically to the deflections of the rest of the structure (curvature is described as "very much of an abstraction"). It deals with a representative group of statically indeterminate problems: the deflections of simple frames; the deflections and stresses of redundant frames; beams, shafts, rings, arches, columns and beam columns (bars under direct thrust and lateral load); and has been the text of courses taught to seniors and advanced engineering students at the University of Michigan. There are 54 problems for the student. The style is close to that of a direct transcript of classroom exposition, salted here and there with statements of a downright quality. There is explicit insistence on logic, and on such points as clarity in rules of sign, in several interesting passages. Nevertheless this second edition of the book is not altogether free from unintended examples of confusion in word meanings, statements of assumptions, and definitions, stated and implied.

The book will continue to be valuable to those who share the author's preference for the method it advocates and expounds, and it will interest those who wish to estimate the place and scope of the method in structural theory. The second edition differs from the first (1931) mainly in a revision of notation to a more orthodox form, and in the addition of sections on piston rings, pipe problems, spiral springs, and the chapter on columns.

Mechanical Properties of Materials and Design

MECHANICAL PROPERTIES OF MATERIALS AND DESIGN. By Joseph Marin, Professor of Mechanics, The Pennsylvania State College, first edition, McGraw-Hill Book Co., Inc., New York, N. Y., 1942. Cloth, 6 × 9 in., viii and 273 pp., 142 figs., $3.50.

REVIEWED BY R. E. PETERSON[5]

A BOOK of this kind should be considered from two points of view—its use in engineering education and in engineering practice.

Concerning engineering education, the author states that he has used the material covered by the book both for a senior elective course and for a graduate course. The first few chapters are largely covered in the usual strength-of-materials course, but perhaps it is advisable to include these as a brief review in starting an advanced course. The latter part (about half) of the book is largely new material, speaking in terms of textbooks, and should be valuable to anyone preparing for design work.

With regard to engineering practice, this book should constitute a useful addition to the technical library of the more progressive engineers and designers. Professor Marin has concerned himself primarily with fundamental bases of design. In spite of the fact that in some cases the basic principles are not fully established, as the author points out, it is the reviewer's opinion that the most important feature of the book is the demonstration of rational approach in the development of design data. Too many engineers apply handbook formulas without knowing the assumptions on which the formulas are based. A study of Professor Marin's book should give the engineer a better appreciation of the difficulties involved in attempting to estimate the strength of a complicated machine part under a combination of operation conditions.

As to specific criticisms, the reviewer has only a few: Page 136, the "straight-line law" is no more than a convenient design *rule*, whereas the word *law* would imply an interpretation of actual failure conditions; page 123, the error due to transverse shearing stresses mentioned in connection with cantilever machines can be dismissed since these stresses are zero at the surface where failure starts; page 128, the difference between axial and bending fatigue strengths depends on the material and can amount to as much as 30 per cent for certain coarse-grained materials;[6] page 143, a value of unity for k_s is found in many cases if the shear energy theory is used.

The foregoing criticisms are obviously of a minor character; considering the entire book, the reviewer regards it to be of high order. It can apparently be used in special courses in engineering curricula and should also find use in industry in the design of critical machine parts.

Hydraulics of Steady Flow in Open Channels

HYDRAULICS OF STEADY FLOW IN OPEN CHANNELS. By S. M. Woodward and C. J. Posey, John Wiley and Sons, Inc., New York, N. Y., 1941. Cloth, 5¾ × 9 in., viii plus 151 pages, $2.75.

REVIEWED BY BRANDON G. RIGHTMIRE[7]

THIS book is intended not only for use as a text in senior and first-year graduate courses, but also as a guide to practicing engineers. The experience of the authors has enabled them in several instances to include valuable practical information or to detail quick methods of computation. These features make the book especially useful to the occasional worker in this field.

Both the stationary and moving hydraulic jump are treated; a convenient graphical solution being given. Backwater curves are discussed at length, starting with two-dimensional, frictionless flow, proceeding to Bresse's method of treating bottom friction in wide channels, and ending with graphical and step methods of wide applicability. An analysis is made of several typical flow problems, a method of attack on more complex problems being thus indicated. The concluding chapters deal with flow at bends and obstructions, and with nonsteady flow which changes so slowly that dynamic effects are negligible. A form of the continuity equation suitable for the latter flow is developed, and application is made to computing water levels in a pool with changing inflow and discharge rates dependent on the water level.

Throughout the book the fundamentals of hydraulics are assumed known. It has thus been possible to make the mathematical developments brief and to discuss at length the physical aspects of the phenomena. In only one instance is the treatment inadequate, in the opinion of the reviewer. Critical flow is introduced without a demonstration that small surface waves in shallow water move at the critical velocity, although this fact is used later in the book. The statement is merely made, without proof, that appreciable changes in level can exist without work being done on the water. This possibility is described as a condition of unstable, rather than neutral, equilibrium.

There are many figures, which beautifully supplement the text. Several worked examples are given, as well as problems. References to additional material are cited in frequent footnotes.

Some Two-Dimensional Aspects of the Ejector Problem

By J. A. GOFF[1] and C. H. COOGAN,[2] PHILADELPHIA, PA.

Several investigators have attempted to analyze the performance of the ejector on a one-dimensional basis. Some doubt exists whether such analyses can lead to a rational ejector design because of the questionable validity of certain necessary assumptions. Recently, consideration has been given to the two-dimensional aspects of the problem, and while a rational design has not yet been evolved, the results attained seem to point in the right direction. The theory of turbulent mixing in jets, developed by Tollmien is used as the basis of the study reported in this paper. Tollmien's analysis of the mixing zone produced by a homogeneous air stream issuing into still air of the same pressure and density is reviewed. The authors then extend the theory to allow for the possibility that the driving and driven fluids may have widely different densities.

Introduction

SEVERAL attempts have been made to analyze the performance of the ejector on a one-dimensional basis. Notable among these are the analyses of Stodola (1),[3] Bošnjaković (2), and Flügel (3). All of these are based on the assumptions of uniform, unidirectional velocity over certain sections of interest and of adiabatic flow between sections. Under these assumptions, equations expressing conservation of mass, conservation of energy, and conservation of momentum are w itten down and solved simultaneously. The solution predicts the variation of flow ratio (ratio by weight of driven to driving fluids) with operating pressures and temperatures, and with various area ratios. It is doubtful whether such one-dimensional analyses can lead to a rational design of the ejector, particularly when efficiency is a principal consideration, because of the questionable validity of some of the necessary assumptions. Nevertheless, they have proved useful in the interpretation of experimental data on conventional ejectors and, in some cases, have led to minor improvements in design.

Recently, attempts have been made to consider the two-dimensional aspects of the problem. The starting point is the theory of turbulent mixing in jets first developed by Tollmien (4) as an application of the Prandtl (5) conception of apparent shear stress and mixing length. While none of these attempts has yet produced a rational design, nevertheless they seem to be pointed in the right direction. The present paper is intended as a contribution to further progress in this direction. Tollmien's analysis of the mixing zone produced by a homogeneous air stream issuing into still air of the same pressure and density is reviewed, paying closer attention to features of special importance in ejector design than did Tollmien himself. The theory is then extended to allow for the possibility that the driving and driven fluids may have widely different densities.

Tollmien's Solution

The first case, treated by Tollmien (4), is that of a plane parallel jet issuing into an atmosphere of the same fluid at the same pressure and density, Fig. 1. Tollmien assumes that the width of the mixing zone and, therefore, the magnitude of the mixing length l increase linearly with distance from the point where

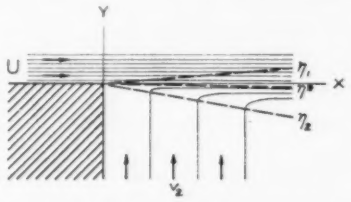

Fig. 1 Tollmien Streamlines

mixing begins. Accordingly, the expression for apparent shear stress becomes

$$\tau = \rho c^2 x^2 (\partial u/\partial y)^2 \quad \ldots\ldots [1]$$

where ρ is the density (assumed constant), c is an empirical constant to be adjusted by comparison with experiment, and u is the x component of the velocity. He then shows that the differential equations, expressing conservation of mass (continuity equation) and conservation of momentum in the x direction together with appropriate boundary conditions, can be satisfied by taking u to be a function of the ratio y/x. Thus, taking

$$u = F'(\eta) \quad (\eta = y/x) \quad \ldots\ldots [2]$$

the continuity equation requires that v, the y component of velocity, be also a function of y/x only, namely

$$v = -F(\eta) + \eta F'(\eta) \quad \ldots\ldots [3]$$

Taking account of Equations [1, 2, 3], the differential equation expressing conservation of momentum in the x direction reduces to

$$F(\eta) + 2c^2 F'''(\eta) = 0 \quad \ldots\ldots [4]$$

Equation [4] is an ordinary differential equation, the general solution of which may be written in the form

$$F/aU = be^{\zeta/2} [-e^{-3\zeta/2} + \cos\theta + f\sin\theta] \quad \ldots\ldots [5a]$$

$$F'/U = be^{\zeta/2} [+e^{-3\zeta/2} - \sin(\theta - \pi/6) + f\cos(\theta - \pi/6)] \quad \ldots [5b]$$

$$aF''/U = be^{\zeta/2} [-e^{-3\zeta/2} - \sin(\theta + \pi/6) + f\cos(\theta + \pi/6)] \quad \ldots [5c]$$

where $\zeta = \eta/a - \eta^*/a$ and $\theta = \sqrt{3}\zeta/2$, a being written for $(2c^2)^{1/3}$ and η^* denoting the solution of $F(\eta) = 0$. The three con-

[3] Numbers in parentheses refer to the Bibliography at the end of the paper.

Presented at the Annual Meeting, New York, N. Y., December 1–5, 1941, of The American Society of Mechanical Engineers.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until January 11, 1943, for publication at a later date. Discussion received after the closing date will be returned.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors and not those of the Society.

stants b, f, η^*/a can be adjusted to satisfy appropriate boundary conditions.

The boundary conditions studied by Tollmien are: (a) Along $\eta = \eta_1$, $u = U$, $v = 0$, $\partial u/\partial y = 0$; ($b$) along $\eta = \eta_2$, $u = 0$, $\partial u/\partial y = 0$. These are equivalent to

$$(a)\ \eta = \eta_1;\ F'/U = 1;\ F/aU = \eta_1/a;\ aF''/U = 0$$
$$(b)\ \eta = \eta_2;\ F'/U = 0;\ aF''/U = 0$$

These five boundary conditions determine η_1/a, η_2/a, and the three constants of integration, η^*/a, b, f.

It happens that the two lower boundary conditions (b) themselves determine the values $\zeta_2 = -1.8498$, $f = 32.052$. With the value of f determined, the upper boundary conditions (a) determine the values of η_1/a, η^*/a, and b. The complete solution is as follows

$$\left.\begin{aligned} \eta_1/a &= 0.9814 \\ \eta^*/a &= -0.1855 \\ \eta_2/a &= -2.0353 \\ b &= 0.01985 \\ f &= 32.052 \end{aligned}\right\} \quad \ldots\ldots\ldots\ldots\ldots\ldots [6]$$

The corresponding velocity profiles at any distance x_0 from the origin are shown in Fig. 2. Tollmien (4) compared the theoretical profile u/U, Fig. 2, with that measured on a large wind-tunnel jet at the Aerodynamic Research Institute, Göttingen, and found that good agreement is obtained on taking $a = 0.0845$. Förthmann (6) investigated the open jet, partially open jet, and partially expanding jet. In the case of the open jet, Förthmann found minor systematic discrepancies from Tollmien's theoretical velocity profiles. Kuethe (7) extended Tollmien's theory to the case where the driven fluid has a velocity U_2 parallel to that of the driving fluid U_1.

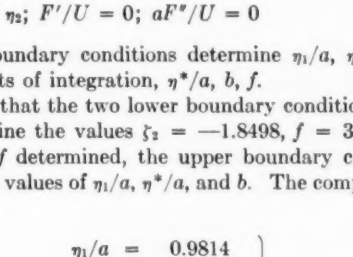

FIG. 2 TOLLMIEN VELOCITY PROFILES

Flow Ratio. This is a quantity which Tollmien neglected to mention, but which is of special interest in connection with the possible application of his analysis to ejector design. It is the ratio of the weight of fluid entering the mixing zone across η_2 between the origin and any section x_0, namely, G_2 (lb per sec), to that entering across η_1 between the origin and the same section x_0, namely, G_1 (lb per sec). Its value is easily computed as follows

$$\frac{G_2}{G_1} = \frac{-x_0F(\eta_2)}{x_0\eta_1U} = \frac{a}{\eta_1}\cdot\frac{F(\eta_2)}{aU} = 0.3868 \ldots\ldots\ldots [7]$$

It is important to note that, according to the Tollmien theory, the flow ratio has the nature of a universal constant, being independent of the velocity U of the driving fluid, independent of the density ρ, and independent of the empirical constant a. Its independence of the magnitude of the velocity U of the driving fluid suggests that the only reason for high values of U in the ejector is to provide the necessary kinetic energy to accomplish compression after mixing.

Kinetic Energy. In order to estimate the loss of kinetic energy due to mixing itself, it is convenient first to calculate separate items as follows:

(a) The kinetic energy crossing η_2 between the origin and any section x_0 per unit of kinetic energy crossing η_1 between the origin and the same section x_0, namely

$$-\frac{a}{\eta_1}\left[\frac{F(\eta_2)}{aU}\right]^3 a^2 = 10^{-2}a^2A \text{ (Fig. 4, } \rho_1/\rho_2 = 1)$$

(b) The kinetic energy crossing x_0 between η_2 and η_1 due to the x component of velocity per unit of kinetic energy crossing η_1 between the origin and x_0, namely

$$\frac{a}{\eta_1}\int_{\eta_2}^{\eta_1}\left(\frac{F'}{U}\right)^3 d(\eta/a) = 10^{-1}B \text{ (Fig. 4, } \rho_1/\rho_2 = 1)$$

(c) The kinetic energy crossing x_0 between η_2 and η_1 due to the y component of velocity per unit of kinetic energy crossing η_1 between the origin and x_0, namely

$$\left\{\frac{a}{\eta_1}\int_{\eta_2}^{\eta_1}\frac{F'}{U}\left[-\frac{F}{aU}+\frac{\eta}{a}\cdot\frac{F'}{U}\right]^2 d(\eta/a)\right\} a^2 = 10^{-3}a^2C$$
(Fig. 4, $\rho_1/\rho_2 = 1$)

(d) The loss of kinetic energy in the mixing zone per unit of kinetic energy crossing η_1 between the origin and x_0, namely

$$1 + 10^{-2}a^2A - 10^{-1}B - 10^{-3}a^2C = 10^{-2}D + 10^{-2}a^2E$$
(Fig. 4, $\rho_1/\rho_2 = 1$)

Numerically, this loss per pound of driving fluid is

$$(0.185 + 0.045a^2)\frac{U^2}{2g}$$

The definite integrals in items (b) and (c) were evaluated by mechanical quadrature aided by graphical integration. For $a = 0.0845$ as found by Tollmien, the second term within the parentheses is negligible in comparison with the first. Hence it appears that the kinetic-energy loss should not exceed approximately 18.5 per cent of the kinetic energy of the driving fluid regardless of the value of a.

Thermodynamics. The Tollmien theory assumes uniform pressure and uniform density throughout the mixing zone. Under these conditions the specific enthalpies of driving fluid, driven fluid, and mixed stream are the same; hence the total thermal energy convected out across any section x_0 between η_2 and η_1 is equal to that convected in across η_1 and η_2 between the origin and the given section x_0. Thus, it is necessary to reject heat of amount

$$-{}_0q_{x_0} = 0.185\,\frac{U^2}{2g} \ldots\ldots\ldots\ldots\ldots [8]$$

per unit weight of driving fluid.

In actual practice, it would be difficult, if not impossible, to provide means of rejecting any considerable quantity of heat from the mixing zone, and the mixing would be very nearly adiabatic. This would require an increase of specific enthalpy in the direction of flow and, therefore, if pressure is constant, a decrease in density. Consequently, the Tollmien theory cannot predict accurately the mixing process occurring in the actual ejector where the kinetic energy $U^2/2g$ must be fairly large in order to accomplish the necessary compression in the diffuser. At low velocities U, of course, this defect in the Tollmien theory is relatively unimportant.

Streamlines. The equation for a streamline is

$$xF(\eta) = \text{const} \quad [9]$$

The general character of the streamline is shown in Fig. 1. The streamline through the origin satisfies the equation $F(\eta) = 0$, and therefore coincides with the straight line $\eta = \eta^*$. Streamlines of the driving fluid are deflected downward at the line $\eta = \eta_1$ and approach the line $\eta = \eta^*$ asymptotically from above. The streamlines of the driven fluid are deflected to the right at $\eta = \eta_2$ and approach the line $\eta = \eta^*$ asymptotically from below. The theory, therefore, appears to deny the existence of mixing because it predicts distinct streamlines for driving and driven fluids, the driven fluid merely being accelerated by the action of a shearing force at the surface of separation $\eta = \eta^*$. However, it is necessary to remember that these are apparent or mean streamlines only, across which there occurs a continuous exchange of matter and momentum, giving rise to the apparent or mean shear stress.

Along a streamline of the driven fluid, the velocity may increase to a value well above acoustic. Still, the line is one of constant pressure and constant density, so that no compressibility effects and, hence, no critical phenomena should be expected. The only limitations of the theory with respect to the magnitude of the velocity U, besides that discussed under "Thermodynamics," appear to be that (*a*) at very low velocities true turbulent motion may not develop, but instead eddies are formed; (*b*) at velocities exceeding twice acoustic, according to Ackeret (8), the surface of separation between driving and driven fluids becomes stable and true turbulent mixing can only commence at some distance downstream from the nozzle end.

Density Effect

Consider an ejector supplied with air at 100 psi, 70 F exhausting a space filled with air at 0.3 psi, 70 F. The mixing-chamber pressure would be expected to approximate 0.3 psi, hence, in a correctly designed nozzle, the driving fluid would expand isentropically to 0.3 psi, —265 F. Thus the densities of driving and driven fluids would be in the ratio $\rho_1/\rho_2 = 530/195 = 2.72$. To this situation, the simple Tollmien theory cannot apply.

It is possible however on the basis of certain reasonable assumptions to extend the Tollmien theory to the case where driving and driven fluids have widely different densities. These assumptions may be enumerated as follows: (*a*) A line $\eta = \eta^*$ separates the mixing zone into two regions, the upper region having uniform density ρ_1 and the lower region, uniform density ρ_2; (*b*) the line of separation is a streamline in each region along which velocity and apparent shear stress are the same on either side; (*c*) the same boundary conditions apply at η_1 and η_2 as in the simple theory.

Now the magnitude of the shear stress at any point is given by

$$\tau = \rho c^2 x^2 \left(\frac{\partial u}{\partial y}\right)^2 = \rho c^2 [F''(\eta)]^2 \quad [10]$$

and it may be assumed that the constant c is independent of density. Hence, along the line of separation ($\eta = \eta^*$)

$$\eta_1^* = \eta_2^* \quad [11a]$$

$$F_1'(\eta^*) = F_2'(\eta^*) \quad [11b]$$

$$\rho_1^{1/2} F_1''(\eta^*) = \rho_2^{1/2} F_2''(\eta^*) \quad [11c]$$

At the upper boundary ($\eta = \eta_1$)

$$\frac{F_1(\eta_1)}{aU} = \frac{\eta_1}{a} \quad [12a]$$

$$\frac{F_1'(\eta_1)}{U} = 1 \quad [12b]$$

$$\frac{aF_1''(\eta_1)}{U} = 0 \quad [12c]$$

At the lower boundary ($\eta = \eta_2$)

$$\frac{F_2'(\eta_2)}{U} = 0 \quad [13a]$$

$$\frac{aF_2''(\eta_2)}{U} = 0 \quad [13b]$$

These boundary equations determine uniquely the constants η_1/a, η_2/a, η^*/a, f_1, f_2, b_1, b_2 for any given density ratio ρ_1/ρ_2. In the foregoing, the subscript 1 refers to the upper region of uniform density ρ_1, the subscript 2 to the lower region of uniform density ρ_2.

As in the simple theory, the quantities $\zeta_2 = (\eta_2/a - \eta^*/a)$ and f_2 are calculable from the two lower boundary conditions; and, since the density ratio does not appear in these, the values of ζ_2 and f_2 are the same as for the simple theory. The procedure followed in evaluating the remaining constants is to assume a value of $\theta_1 = \frac{\sqrt{3}}{2}\zeta_1$ and compute the corresponding value of f_1 using Equation [12*c*]; then to compute the values of b_1/b_2 and ρ_1/ρ_2 from Equation [11*b*] and [11*c*]; finally to compute η^*/a and b_1 from Equations [12*a*] and [12*b*]. After these constants have been determined, the corresponding value of G_2/G_1 can be computed from

$$\frac{G_2}{G_1} = \frac{\rho_2}{\rho_1} \cdot \frac{a}{1} \cdot \frac{F_2(\eta_2)}{aU} \quad [14]$$

Table 1 summarizes these calculations.

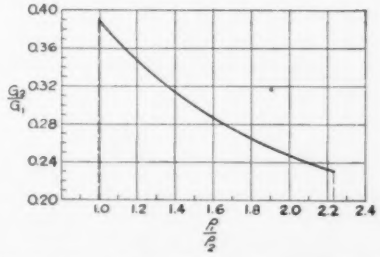

Fig. 3 Flow Ratio Versus Density Ratio

Flow Ratio. Fig. 3 shows the variation of flow ratio G_2/G_1 with density ratio ρ_1/ρ_2. As the density of the driving fluid increases relative to that of the driven fluid, the weight of driven fluid per unit weight of driving fluid decreases. Referring to the examples at the beginning of this section, if the driving fluid be preheated before being supplied to the ejector, its density will be decreased and a higher flow ratio will be obtained. Whether or not a net advantage results, considering the extra energy which must be

supplied, is a question which may be deferred until the applicability of the analysis to ejector design is fully demonstrated.

Kinetic Energy. Referring to the previous discussion of kinetic energy, the various ratios mentioned there can be calculated using the data in Table 1. It is necessary to divide the range of integration into subranges, η_2 to η^* and η^* to η_1; for the integral in the first subrange must be divided by the density ratio ρ_1/ρ_2. Also item (*a*) of the previous section on "Kinetic Energy," requires division by ρ_1/ρ_2. The results are given by the curves in Fig. 4, from which it appears that the loss of kinetic energy due to mixing decreases with increasing density ratio. This might

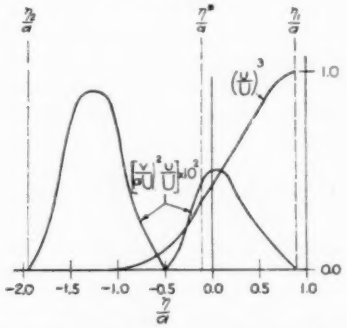

FIG. 5 VARIATION OF KINETIC ENERGY WITH η/a

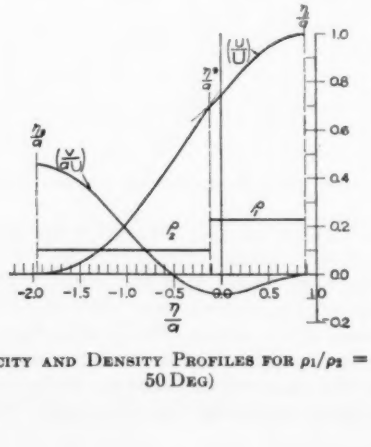

FIG. 6 VELOCITY AND DENSITY PROFILES FOR $\rho_1/\rho_2 = 2.233$ ($\theta_1 = 50$ DEG)

have been expected since the flow ratio also decreases with increasing density ratio. For a density ratio $\rho_1/\rho_2 = 2.233$, for example, the kinetic energy loss is

$$(0.133 + 0.042a^2)\frac{U^2}{2g}$$

per pound of driving fluid.

Fig. 5 is of some interest as showing the variation with η/a of the kinetic energy crossing x_0 on both the x and y components of velocity. Strictly speaking the ordinates to the left of η^*/a must be divided by the density ratio ρ_1/ρ_2 which, in Fig. 5, has the value 2.233.

SUMMARY

Fig. 6 shows velocity profiles similar to those of Fig. 2, but for a density ratio $\rho_1/\rho_2 = 2.233$. It is interesting to note the discontinuities in slope at η^*/a.

Fig. 6 also illustrates an important feature of the solutions obtained for density ratios different from unity by showing the assumed variation in density itself. In view of the analogy between heat transfer and momentum transfer in turbulent flow an abrupt change in density at η^* is not strictly compatible with a continuous velocity distribution. There are reasons to believe, however, that the solution is a good first approximation to the truth.

An apparatus has been designed to conform as closely as possible with the boundary conditions studied by Tollmien and has been tested with air as driven and driving fluid. The velocity of the driving fluid was arbitrarily taken as U = 300 fps, which dictated a pressure ratio of 0.95 for the nozzle. The driven air was supplied at atmospheric pressure by throttling some of the air from the pressure before the nozzle, hence, a density ratio of 1.015 in the mixing chamber. In calculating various dimensions, the value $a = 0.0845$ found by Tollmien was used. Beyond the mixing chamber proper, a convergent passage was added, the walls of which were made streamlines, according to the extended Tollmien theory, this passage being terminated at the point where the y component of velocity vanishes.

The experimental measurements showed a velocity distribution in substantial agreement with the theoretical; and a flow ratio of 0.34 was measured as against 0.382 predicted. It seems reasonable, therefore, to believe that the present theory can be used as a basis for design, though much additional experimentation is required.

Experimental Determination of the Isostatic Lines

By AUGUSTO J. DURELLI,[1] CAMBRIDGE, MASS.

In this paper a direct method for obtaining the isostatics or stress trajectories is described. These lines indicate the directions of the principal stresses. The procedure used by the author can be applied almost without regard to the geometrical form of the object under stress. It also possesses the advantage in that the test is nondestructive and that in most cases it will yield values of the stress magnitudes within 10 or 15 per cent of the correct values. The technique consists in covering the surface of the body with a thin coat of lacquer which becomes brittle upon hardening. If the object being tested is painted under zero load and then stressed after the coating has hardened, the layer of lacquer will crack along lines perpendicular to the maximum tensile strain. The companion set of trajectories at right angles can usually be formed through relaxation. As an aid in photoelasticity this procedure has great possibilities as it eliminates the necessity for determining the isoclinic lines which are difficult to obtain.

Introduction

AT EVERY point in a two-dimensional system of stress there are two principal stresses, whose directions are at right angles. The stress trajectories or isostatics form orthogonal curves whose characteristic is that, at every point through which they pass, the principal-stress directions are normal and tangential to them. In order to construct the stress trajectories, one must know the directions of the principal stresses at all points in the field. However, because the directions of the principal stresses and principal strains coincide, the latter may be used for establishing the isostatics.

In the following paragraphs the author describes a direct method for utilizing the strains set up in a stressed body for constructing the stress trajectories.

General Application

If the surface of an unstrained body is painted with a thin coating of brittle lacquer, then when the load is applied the lacquer will follow the deformations of the body exactly and, if the strain is sufficient to rupture the lacquer, cracks will be formed in directions normal to the principal tensile strains, provided that the following conditions are fulfilled:

1 There must be perfect adhesion between the lacquer and the surface of the strained body.

2 The lacquer must be brittle and will rupture at a strain below the yield point of the material upon which it has been painted.

3 The lacquer must be able to resist small changes in temperature and humidity to avoid crazing.

With this procedure two sets of information can be obtained. Because the cracks follow the direction normal to the principal tensile strain, one family of the stress trajectories can be formed by loading a structure; and the family at right angles can be obtained by relaxation, that is, by releasing the load. In addition, an approximate value (usually within from 10 to 15 per cent of the correct value) of the strain intensity can be found because the lacquer will first crack at the region of highest strain and continue to crack at other regions as they reach the same strain, so that, by following the order of appearance of the cracks, it is possible to calculate the degree of the strain. The spacing or proximity of neighboring cracks will serve to give an indication of the strain at which the first cracks appear, by comparison with some object of known stress distribution. See Fig. 1. A convenient form of calibration specimen is a small cantilever beam, as shown in Fig. 2, in which the stress distribution varies linearly if a concentrated load is applied at the free end.

Strain-concentration factors can be determined very simply by this method without resort to the calibration specimen, provided that one knows the relation between the applied load and the strain at some point on the object under investigation. The point at which the strain is known can then be used as a reference. The loads corresponding to the appearance of the first cracks at the points of strain concentration and at the point of reference can be measured, and the ratio of these loads represents the value of the strain-concentration factor. A single test is usually insufficient for a representative value of the factor but a reasonably accurate value can be obtained as the mean of several observations.

In making use of this method of stress analysis the usual procedure is to spray a thin coating of lacquer on the surface of the object under investigation. This is usually allowed to harden for four or five hours. There are several substances which can be used for the coating (1 to 5)[2] but the writer has found those supplied by the Magnaflux Company (6) under the name of "Stresscoat" to be most convenient because they fulfill all the fundamental requirements and in addition they dry bubble-free without the necessity of heating the surface on which they have been sprayed.

The lacquer is usually applied to prototypes which in most cases are made of metal and in consequence are opaque. If the surfaces are brightly finished, photographs of the crack patterns can be made conveniently with reflected light: but if the surfaces are rough, an undercoating of aluminum paint is applied to produce the reflecting surface.

Although in many cases it is more desirable to work with prototypes, there are certain applications in which models can be used to great advantage. For large structures small scale models represent a great reduction in cost and at the same time permit one to apply materials which are easier to machine and which have a lower value of the elastic modulus in relation to the pro-

portional limit. This latter consideration is of some importance since it permits a greater strain for a given stress and a corresponding increase in the number of isostatics and the area covered. As an example one might mention that the unit strain corresponding to the yield point in mild steel is about 0.001, whereas the corresponding strain in Bakelite is about 0.01, and for celluloid even greater.

When models are made from materials such as Lucite, Bakelite, and celluloid, which are transparent, photographs of the isostatics can often be made with transmitted light (9). If the models are made from flat plates of these materials then the use of transmitted light is simple and preferable.

APPLICATION TO PHOTOELASTICITY

The possibility of using the brittle lacquer on transparent flat plates at once suggests its application as an aid in photoelasticity. With present practice in photoelasticity, the use of the relatively sensitive synthetic resins is almost universal and the isochromatic lines giving the difference between the principal stresses can be determined conveniently and precisely. However, if one wishes to find the principal-stress directions, one must first locate the isoclinic lines and from these construct the stress trajectories. This is at best a somewhat uncertain procedure and represents the most inaccurate part of the photoelastic analysis. It is difficult to determine the exact position of the isoclinic lines, which must be located one by one, and the subsequent construction of the isostatics introduces still further possibility of error. In contrast to the photoelastic method of determining the stress directions, the application of brittle coatings to photoelastic models offers a relatively quick, easy, and direct means of obtaining the stress trajectories which can be recorded photographically over the whole field at once.

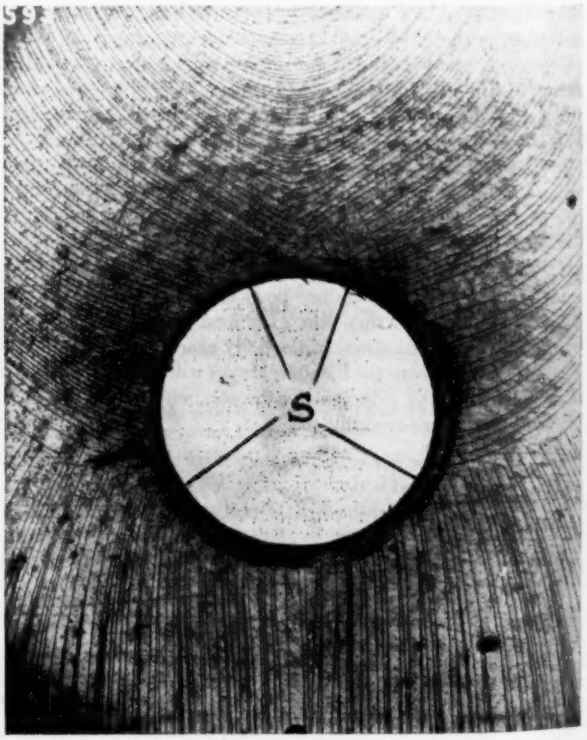

FIG. 3 ISOSTATICS NEAR THE POINT OF LOADING IN A SIMPLE BEAM OF LUCITE WITH A CIRCULAR HOLE
On the boundary there are four singular points. Photographed with transmitted light.)

In applying the lacquer to photoelastic models it is not necessary to use an intermediary coating. After testing, the surface is washed in succession with a solution of gasoline and oil, and gasoline alone. F. Stern also obtains very good results with turpentine alone or with dye in solution. The isostatics can then be photographed in a polariscope, after removal of the polarizing elements, or the model may be used in exactly the same manner as a photographic plate. If the latter procedure is adopted for making prints directly, the coated side of the model should be placed next to the printing paper. Since handling of the model is likely to chip off some of the coating it is advisable to make a photographic negative on film and to use this for printing.

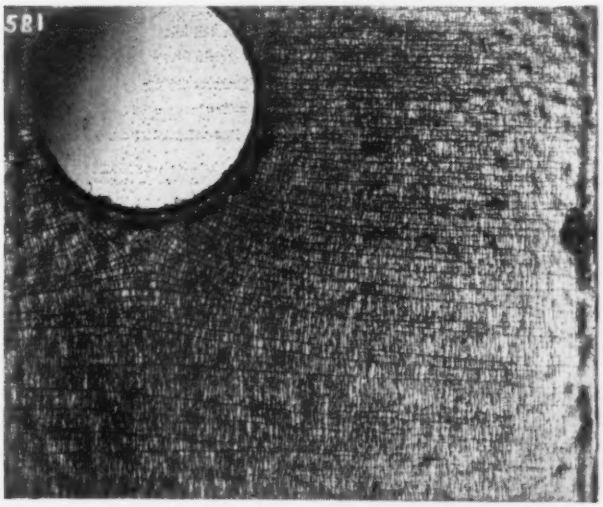

FIG. 7 ISOSTATICS AROUND A CIRCULAR HOLE IN A PLATE SUBJECTED TO PURE BENDING NORMAL TO THE PLANE OF THE PLATE
(The same set of isostatics prevails all along the boundary.)

Illustrations of the isostatics obtained on various models are shown in Figs. 3 to 6. These all represent cases of plane stress but the usefulness of brittle lacquer is by no means limited to such cases. There are other problems in which models of transparent material having a low elastic modulus can be used to great advantage, either as an aid to photoelasticity or an extension beyond the limits of the optical method of stress analysis. One problem of this nature is the determination of the stress condition around a discontinuity in a plate subjected to bending (7). Fig. 7 shows such an example with the directions of the principal stresses indicated at all points on the surface of the plate. A note of contrast should be observed between this picture and those in Figs. 3 and 6 where singular points are indicated. The absence of the singular points shows that there is no reversal of stress around the edge of the hole as in the case of pure tension.

As a point of academic interest, mention must be included of the fact that photographs can be made of photoelastic models in which the isostatics are superimposed on the isochromatics.

Fig. 8 illustrates two such sets of lines in a double-ended eyebar. The procedure for taking the picture was extremely simple; the model was first coated with the lacquer, which was allowed to dry, and then it was loaded in the testing machine of the polariscope.

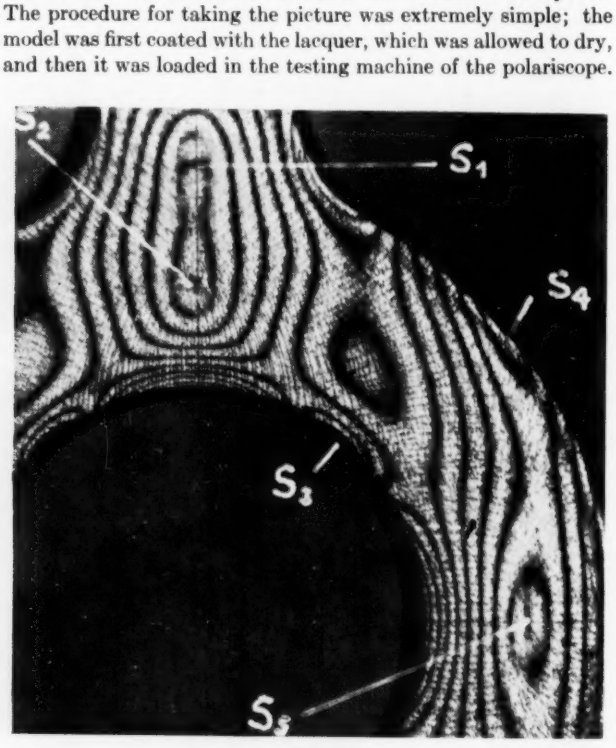

FIG. 8 ISOSTATICS AND ISOCHROMATICS IN AN EYEBAR

FIG. 10 ISOSTATICS IN AN EYEBAR
The brittle coating has not broken around the singular points.)

The usual photoelastic picture was taken with the crack pattern of the lacquer superimposed upon it. The interest in this procedure lies in the fact that it provides all the necessary information for determining the individual principal stresses and their directions at all points in the model.

So far in this discussion, the fact that the brittle coating cracks in a direction normal to the principal strain has been stated but no proof of the fact has been offered. If the illustrations are studied several proofs will appear. The fact that the cracks appear normal to free boundaries (where there is only one stress parallel with the boundary) and across the shank of the eyebar in Fig. 10, where a condition of pure tension exists, is proof for cases

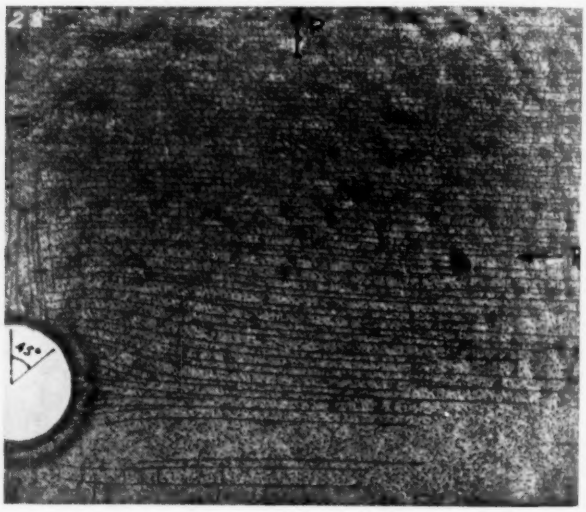

FIG. 9 PROOF THAT THE LACQUER BREAKS NORMAL TO THE PRINCIPAL TENSILE STRAIN IN COMPLEX STATE OF STRESS
(The specimen is under pure shear. The lines of fracture of the lacquer are normal to the tension.)

of stress in one direction. For the condition of a complex state of stress similar proof is offered in Fig. 9 which shows the pattern in a model subjected to pure shear by the application of uniform and equal tension and compression in directions at right angles. Here the cracks are also normal to the tension (remote from the hole).

Limitations

A limitation in the use of the brittle-lacquer method of stress analysis arises from the fact that below a certain strain (about 0.0007 in. per in.) the lacquer will not rupture. For two-dimensional problems the principal strains are given by the equations

$$\epsilon_1 = (1/E)\ (\sigma_1 - \nu\sigma_2)$$

$$\epsilon_2 = (1/E)\ (\sigma_2 - \nu\sigma_1)$$

where ϵ_1 and ϵ_2 = the principal strains; σ_1 and σ_2 = the principal stresses; E = the modulus of elasticity; ν = Poisson's ratio. For Bakelite, $E \sim 700{,}000$ psi and $\nu = 0.36$, so that

$$\sigma_1 - 0.36\ \sigma_2 > \sim 500 \text{ psi}$$

to obtain the minimum strain of 0.0007 in. per in.

Even though there may be no stress at all in the direction normal to an isostatic, nevertheless the strain may produce a crack in the lacquer. The concentrated load on a semi-infinite plate is an example of such a case. See Fig. 12. If one considers the point of load application (for this case) as the point of reference in a system of polar co-ordinates then the principal stresses σ_1 and σ_2 will be the radial and tangential stresses, respectively.

The strain ϵ_1 produces the isostatics of set No. II and the strain ϵ_2 the isostatics of set No. I. The stress σ_2 is zero so that the strain ϵ_2 is due to stress σ_1. In other words, both sets of isostatics are produced by σ_1 which is the only stress acting. When the load is applied σ_1 is a compression but it acts like a tension at

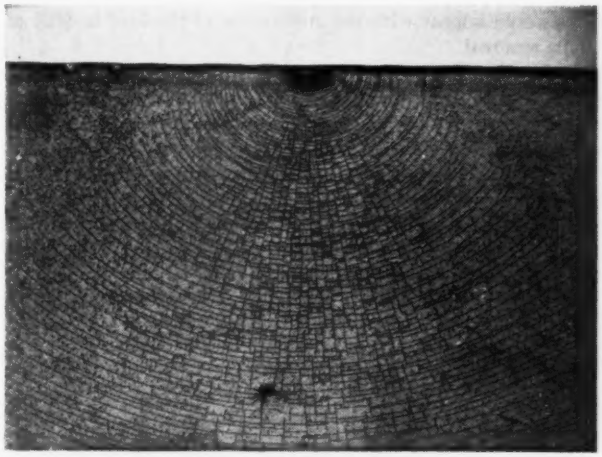

Fig. 12 Isostatics in a Plate of Bakelite, 3 × 1 × 0.25 In., Loaded on the Boundary by Means of a Cylinder 5/16 In. in Diameter

(Near the point of load application the stress is high and the lacquer has broken.)

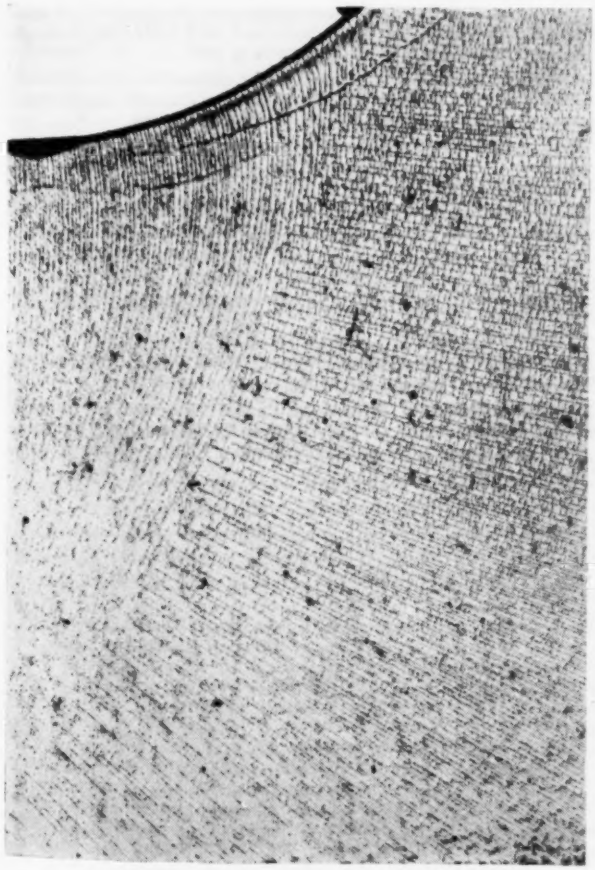

Fig. 13 Isostatics in an Eyebar

(The picture has been taken in the parallel field of the polariscope and enlarged about three and one-half times.)

Fig. 14 Isostatics in an Eyebar

(Printed directly from the transparent model of Bakelite. Enlarged about three times.)

right angles in producing ϵ_2. When the load is removed the relaxation of σ_1 produces the effect of a tension by creating the strain ϵ_1 directly.

A case might arise in which σ_2 would be a small compression such that $(\sigma_2/E) < (\nu\sigma_1/E)$. Under these circumstances although σ_2 would be a compression the strain ϵ_2 would be an extension and cracks would appear with the application of the load instead of with its removal.

The fact that the isostatics appear in the lacquer sooner at some regions than at others is a sign of greater strain but not always of greater stress. At the singular points, for instance, the stress required to produce cracks in the coating on a Bakelite model is about 800 psi; whereas if one of the principal stresses is zero the cracks will appear for stresses corresponding to about 500 psi. However, these considerations do not alter the fact that the directions of the principal stresses and principal strains coincide or that the singular points are the same for both.

To obtain the real value of the stress it would be necessary to make two tests, the first one giving ϵ_1 and the second one giving ϵ_2 by relaxation of the load.

Singular Points

At singular points, since $\sigma_1 = \sigma_2$, both principal stresses must be greater than about 800 psi to produce a crack. When these occur in regions of relatively low stress, it is often impossible to obtain the complete picture of the isostatics without overstressing some regions of the specimen.

Although there are several kinds of singular points (8), usually only those of the first and second order can be found. For example, in Fig. 11, S_2 and S_5 are singular points of the first order and S_1 is of the second order. On the boundaries the singular points can be mixed. In any case it is easy to recognize the type and to complete the picture of the isostatics.

This procedure is illustrated in Figs. 10 and 11 which show, respectively, the experimental determination of the isostatics and the completed diagram in which for clearness one family of curves has been put in with dotted lines.

Conclusions

Although the author does not claim that this method of stress analysis will by any means provide a solution to all problems, he feels that it is of wide use and application. The following are the general conclusions which can be drawn from his experience with it:

1 It has the advantage of being applicable to bodies of all kinds of irregular contour in three dimensions and will yield information where all other methods fail.

2 It is a method easy to apply and requires no very complicated apparatus.

3 It is nondestructive in character so that a part may be tested without impairing it for subsequent service.

4 As applied to photoelasticity it removes one of the major difficulties and inherent sources of error in that type of stress analysis.

5 One should be careful in interpreting the results to realize that the crack pattern formed is merely a function of strain and that stresses can be derived from these rather than observed directly.

Acknowledgment

The study described in the foregoing paragraphs was made at the Massachusetts Institute of Technology where the writer was a guest during 1940 and 1941. The author wishes to express his thanks and appreciation to authorities of the Massachusetts Institute of Technology for the privileges extended to him and in particular to Prof. W. M. Murray and to Prof. A. V. de Forest. To Mr. Ellis and Mr. Stern he is very grateful for assistance in the application of the brittle lacquer to problems in photoelasticity.

The Photoelastic Analysis of Transverse Bending of Plates in the Standard Transmission Polariscope

By D. C. DRUCKER,[1] ITHACA, N. Y.

In this paper the ideas of three-dimensional photoelasticity are applied to the analysis of plates under transverse bending, resulting in a simple photoelastic method, employing the standard two-dimensional transmission polariscope. The procedure used is to "freeze" a fairly high initial tension in bakelite or similar material, cut out the model at some angle to the direction of the tension, bend, and observe. Results of various tests are given; photographs of two cases, the circular hole and the semicircular notch, are included. Stress-concentration factors are also obtained and analyzed. The problem of the thick plate as contrasted with the thin plate, assumed in the usual theory, is discussed briefly.

Introduction

A NUMBER of methods have been proposed for the photoelastic analysis of plates under transverse bending, i.e., plates bent out of their plane, and other theoretically possible methods will occur to the reader as the problem is considered. However, until recently with the work of Goodier and Lee,[2] who used a reflecting foil in the middle plane of the plate, no successful method of analysis had been carried out accurately. Their procedure, in addition to requiring the cementing of a celluloid "sandwich," which is especially difficult in the important regions of stress concentration, does not have one very desirable feature—accurate usable photographic record of the results cannot be obtained.

From the standpoint of clarity of image, convenience, and accuracy of measurement, it is best to use transmitted light. Unfortunately, if a plate, originally free of stress, is bent and placed in a plane or circular polariscope so that light passes through in a direction perpendicular to the plate, as shown in Fig. 1(*b*), nothing can be observed. The tension side cancels the compression side and the net result is zero for both isochromatics and isoclinics. However, a standard transmission polariscope can be used if the following proposed procedure is employed.

First, a state of uniaxial tension is "frozen" in a large plate of bakelite or similar thermosetting material. This is done in the usual way. The bakelite is heated to about 110 C, loaded in pure tension, and then cooled under load. When down to room temperature, the load is removed. In so far as optical measurements are concerned, a state of simple tension remains in the bakelite which is not disturbed by slow and careful machining.[3] The stress which apparently exists in the material will be called $\sigma_t = n_t C/2h$, where n_t is the fringe order observed due to the frozen tension, C the room-temperature stress-optical coefficient in pounds per square inch for 1-in. thickness, and h the half thickness of the plate. The model is then cut from this larger plate at some angle to the direction of the tension, Fig. 1(*a*). When this smaller plate is placed in a circular polariscope and bent, it will be found that the fringe order appearing on the screen will

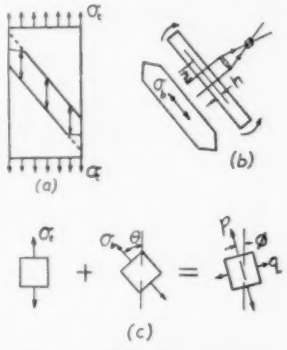

Fig. 1 Basic Procedure

increase as the bending moment increases but not in direct proportion. The tension side in bending no longer cancels the compression side.

Theory

The observed increase in retardation is a measure of the bending stresses produced. To find the relationship, it will first be assumed that the smaller plate is a thin rectangular plate under pure bending. As shown in Fig. 1(*c*), a state of pure bending has been added to a state of simple tension, the direction of the bending stress σ_b, at some angle θ to the direction of the tensile stress σ_t. The combination of these two states of stress at any point in the plate may be represented by the resulting principal stresses, p and q, and their orientation ϕ, say, with respect to the known direction of the tensile stress.

If light is passed through the plate perpendicularly, all that can be obtained photoelastically is something about the difference between the principal stresses p—q, and something about the orientation. Considering a co-ordinate z, measured from the middle plane of the thin plate, σ_b varies linearly with z and can be written as $\frac{\sigma_{bm}}{h}z$, where σ_{bm} is the value of the maximum bending stress. Terms p, q, and ϕ can then be expressed as functions of z, the frozen tension, and the maximum bending stress

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until January 11, 1943, for publication at a later date. Discussion received after the closing date will be returned.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors and not those of the Society.

[3] "The Fundamentals of Three-Dimensional Photoelasticity," by M. Hetényi, Journal of Applied Mechanics, Trans. A.S.M.E., vol. 60, 1938, p. A-149.

$$p - q = \sigma_t \sqrt{1 + \left(2\frac{\sigma_{bm}}{\sigma_t}\cos 2\theta\right)\frac{z}{h} + \left(\frac{\sigma_{bm}}{\sigma_t}\right)^2\left(\frac{z}{h}\right)^2} \quad \ldots [1]$$

$$\tan 2\phi = \frac{\left(\frac{\sigma_{bm}}{\sigma_t}\sin 2\theta\right)\frac{z}{h}}{1 + \left(\frac{\sigma_{bm}}{\sigma_t}\cos 2\theta\right)\frac{z}{h}} \quad \ldots [2]$$

Were the orientations of the principal stress unchanged through the thickness, the retardation would add up algebraically as the light traveled through the model. The fringe order resulting would be

$$n = \int_{-h}^{+h} \frac{p - q}{C}\, dz \quad \ldots [3]$$

If the orientation changes continuously through the thickness as it does in this case, then the retardation will be somewhat higher than given by this expression, but the difference will be inappreciable in the working range that will be used[4] ($\sigma_{bm}/\sigma_t < 4$). Integrating Equation [3], and factoring out $n_t = \sigma_t 2h/C$, we obtain

$$n = n_t \left\{\frac{1}{4\frac{\sigma_{bm}}{\sigma_t}}\left[\left(\frac{\sigma_{bm}}{\sigma_t} + \cos 2\theta\right)\sqrt{1 + 2\frac{\sigma_{bm}}{\sigma_t}\cos 2\theta + \left(\frac{\sigma_{bm}}{\sigma_t}\right)^2}\right.\right.$$
$$\left. + \left(\frac{\sigma_{bm}}{\sigma_t} - \cos 2\theta\right)\sqrt{1 - 2\frac{\sigma_{bm}}{\sigma_t}\cos 2\theta + \left(\frac{\sigma_{bm}}{\sigma_t}\right)^2}\right]$$
$$\left. + \sin^2 2\theta \left\{\sinh^{-1}\left(\frac{\frac{\sigma_{bm}}{\sigma_t} + \cos 2\theta}{|\sin 2\theta|}\right) + \sinh^{-1}\left(\frac{\frac{\sigma_{bm}}{\sigma_t} - \cos 2\theta}{|\sin 2\theta|}\right)\right\}\right\}$$

$$n = n_t F(\sigma_{bm}/\sigma_t, \theta) \quad \ldots [4]$$

The retardation is thus equal to the retardation in the frozen plate before bending, multiplied by a function of the ratio of the maximum bending stress to the apparent frozen tensile stress and of the angle between their directions.

The preceding discussion is based upon bending in one direction only. In the general case there are two principal bending moments each of which, for thin plates, gives rise to linear distributions of bending stress. If σ_b is taken as representing the difference between the principal bending stresses and as acting in a principal direction, then the foregoing reasoning and results carry over without further change. The notation $(p-q)\sigma_b$ will be used in places where σ_b might be misinterpreted. Transverse shearing stresses which may appear will not affect the retardation.

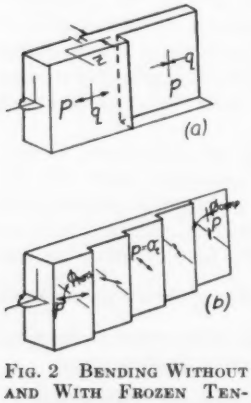

FIG. 2 BENDING WITHOUT AND WITH FROZEN TENSION σ_t
[(a) Without, and (b) with frozen tension.]

Let us now study the light as it passes through the bent plate. First suppose that the entering light is plane-polarized, the direction of vibration coinciding with the p direction of principal stress on entrance to the model. In the case of bending without initial frozen tension, Fig. 2(a), the direction of vibration coincides with the tension direction for the first half thickness of the plate, with the compression direction for the second half, and there is no change in orientation. In the case of initial tension, Fig. 2(b), the result is quite different. The orientation of the p direction changes continuously through the thickness and, providing the rate of change is not too rapid ($\sigma_{bm}/\sigma_t < 4$) for all practical purposes, the vibration will be in the p direction at every point in the model.[4] If the entering light has components in both the p and q directions, these components, with but negligible change in amplitude, will follow their respective directions about as they rotate.

From Equation [2]

$$\tan 2\phi_{tens} = \frac{\frac{\sigma_{bm}}{\sigma_t}\sin 2\theta}{1 + \frac{\sigma_{bm}}{\sigma_t}\cos 2\theta} \quad \ldots [5]$$

$$\tan 2\phi_{comp} = \frac{-\frac{\sigma_{bm}}{\sigma_t}\sin 2\theta}{1 - \frac{\sigma_{bm}}{\sigma_t}\cos 2\theta} \quad \ldots [6]$$

$$\sin 2\theta = \frac{\left(\frac{\sigma_{bm}}{\sigma_t}\right)^2 - 1}{2\frac{\sigma_{bm}}{\sigma_t}}\tan 2(\Delta\phi) \quad \ldots [7]$$

where $\Delta\phi = \phi_{comp} - \phi_{tens}$

EXPERIMENTAL PROCEDURE

Various experimental procedures can be worked out on the basis of the theory. For a complete analysis of a plate, the principal bending stresses and their orientations must be found at every point. In practice, only the maximum values, which occur at the surface of the plate, need be considered. Photoelastically, using the transmission-type polariscope, in a manner similar to that used in the case of plane stress, only the difference between the principal bending stresses at the surface, $(p-q)\sigma_{bm}$ and their orientation θ, can be found.

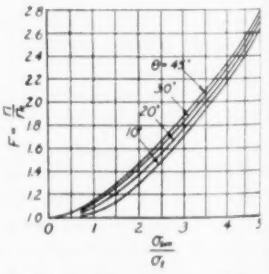

FIG. 3 RETARDATION AS FUNCTION OF RATIO OF MAXIMUM BENDING STRESS TO TENSILE STRESS, AND OF THE ANGLE BETWEEN THEIR DIRECTIONS

If θ is known, as it will be at most important points (free boundaries, axes of symmetry, and regions away from disturbance), one measurement is sufficient to determine $(p-q)\sigma_{bm}$. The simplest procedure is to measure the retardation n. Term n_t and the corresponding stress σ_t are known throughout the plate from measurements made before it is bent, so that the graph, Fig. 3, can be used directly. Values of θ from 0 to 45 deg are sufficient, for in so far as the function F is concerned, θ is the smallest angle between either of the principal bending stresses and the direction of the frozen tension. Values ± 20 deg, 90—20 deg = 70 deg, and —70 deg all lead to the same value of F.

As can be seen from Equations [5], [6], and [7], measurement of ϕ_{tens}, ϕ_{comp}, or $\Delta\phi = (\phi_{comp} - \phi_{tens})$ would also determine $(p-q)\sigma_{bm}$. Independent rotation of the polarizer and analyzer of a plane polariscope is required to find the first two. When the light passing through the model is extinguished at a point where the fringe order is fractional, the polarizer must be passing light

[4] "Stress Analysis by Three-Dimensional Photoelastic Methods," by D. C. Drucker and R. D. Mindlin, *Journal of Applied Physics*, vol. 11, 1940, pp. 724–732.

vibrating in a principal direction on entrance to the model, and the analyzer stopping the light vibrating in the rotated position of this principal direction on exit. The orientations must be determined by trial and, when found, the angle reading on the polarizer or analyzer gives a ϕ from which $(p—q)\sigma_{bm}$ can be computed. Such a procedure is obviously tedious and rather inaccurate. Term $\Delta\phi$ on the contrary can be measured easily if the retardation n is a whole number. At such a point, there will be a position of the analyzer which will extinguish the light for any position of the polarizer. The angular rotation of the analyzer from the original crossed position with the polarizer is the angle $\Delta\phi$. Unlike the corresponding plane-stress measurement, the polarizer does not have to be rotated.

For cases in which θ is known, angular measurements cannot compare in simplicity with measurement of retardation. An isochromatic, or fringe, photograph taken in a circular polariscope provides complete information and a permanent record.

At points where θ is not known, two independent measurements must be made. Two angles will suffice. The point-by-point investigation, using a plane polariscope and independent rotation of analyzer and polarizer just described, will give the information. However, measurement of retardation (i.e., a fringe photograph) and $\Delta\phi$ is much more convenient and accurate. As can be seen from Fig. 3, a 5-deg error in θ has a small effect on the retardation n, in the working range of $(p—q)\sigma_{bm}$ (roughly 1.3 to $4\sigma_t$). If θ is not known as closely as this, a value is assumed, the graph used to obtain a σ_{bm} which is substituted in Equation [7] with the measured value of $\Delta\phi$. This determines θ more accurately, which in turn enables more accurate determination of σ_{bm}. The final value is approached very rapidly. In many cases, one try will be sufficient; in most cases no more than two will be required.

The accuracy of work that can be expected, judging from Fig. 3, is not much less than that obtainable in photoelastic analysis of plane stress of the same precision of measurement. High accuracy, within 1 or 2 per cent, is possible if desired.

Check and New Experiments

Although the basic theoretical work had already been checked roughly for combined tension and torsion, it seemed desirable to obtain further experimental verification of the results.

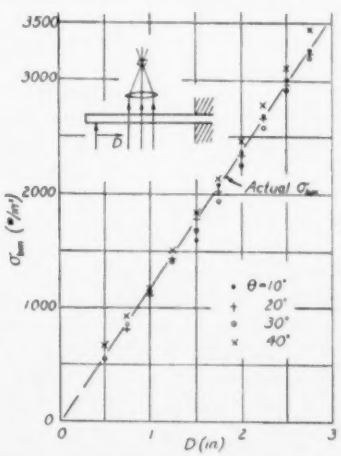

Fig. 4 Cantilever Bending as a Check for Theory

Plates in cantilever bending were used. The transverse shear stresses appearing have no effect on the retardation. Results of one series of tests on plates with four different values of θ are shown in Fig. 4. The points were obtained by computing the bending stress from the measured retardations using the graph of Fig. 3. The straight line gives the bending stress computed from the load and dimensions of the plate. In the range in which this work should be done, the error does not exceed 5 per cent.

The nearer the angle θ is to 45 deg, the smaller will be the bending stress that can be measured accurately.

Having established the accuracy and feasibility of the method on these test cases, the next step was to take a more complicated but well-known case. The bending of a thin plate with a circular hole has been solved analytically by Goodier[5] and checked at least partially by photoelastic and strain-gage measurements. A number of such plates were therefore made. The holes were bored carefully on a lathe, after it was found that drilling released

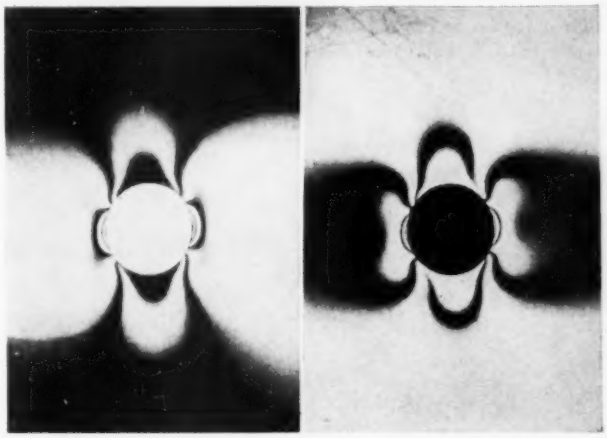

Fig. 5 Circular Hole in Plate Under Pure Bending

part of the frozen initial stress. Fig. 5 shows a typical case. The fringe patterns for both dark and light fields were obtained, for unless both are taken, it is not possible, without accurate scale measurements, to be sure that the true edge of the hole appears on the photograph. Errors of 20 per cent in regions of stress concentration are easily possible on this count alone if small models are used.

The results of a series of tests on different-sized holes in a $1^1/_8 \times {}^1/_4$-in. bakelite plate are shown in Fig. 6, indicating the precision that is possible in this work. The photographs were measured with a traveling micrometer, and care was taken to insure that the edge appearing on the photograph was actually the edge, and if not, where the edge really was. The agreement for the three different loads for the $^3/_8$-in-diam hole is very close. Precision of this order would, of course, not be required in a practical problem.

Analysis of Results

Fig. 7 shows the distribution of the difference between the maximum principal bending stresses all across the net section of the plate on the basis of the maximum bending stress in the gross section away from the hole being unity. Although two other series of tests checked these curves to within about 5 per cent, the results must be carefully scrutinized. The stress-concentration factors, which are based on the gross section, increase as the diameter of hole gets smaller, instead of decreasing as would normally be expected. The value of 2.3 for the $^3/_8$-in. hole is roughly what would be figured on the basis of Goodier's solution and checks with the experimental value obtained by Lee[2] using the reflection method. However, values of 2.5 for the $^1/_8$-in. hole

[5] "The Influence of Circular and Elliptic Holes on the Transverse Flexure of Elastic Plates," by J. N. Goodier, *Philosophical Magazine*, series 7, vol. 22, 1936, pp. 69–80.

and 2.4 for the 1/4-in. hole are far from the 1.8 predicted by the infinite-thin-plate theory.

The reason for the difference seems to lie in the "thinness" of the plate. The thin-plate theory postulates a plate whose thickness is very small compared to its lateral dimensions and the radius of curvature of any portion of the boundary. In the case of the hole in a plate, the diameter of the hole must be a number of times the thickness of the plate for the theory to apply closely. A 1/8-in-diam hole in a 1/4-in. plate certainly does not satisfy this condition, but a 3/8-in-diam hole might not involve large error. Consideration of the theory of moderately thick plates[6] shows that, although the thin-plate analysis satisfies the conditions of no moment and resultant force per unit of length on the free boundary of the hole, the stresses left on the boundary are as high as 1/2 the maximum stress in the plate for the small ratios of diameter to thickness used in the experiments.

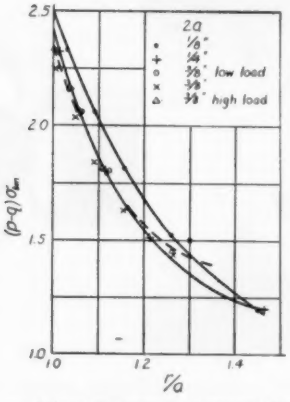

FIG. 6 RESULTS OF MEASUREMENTS ACROSS NET SECTION NEAR BOUNDARY OF HOLES
(Refer to Fig. 7.)

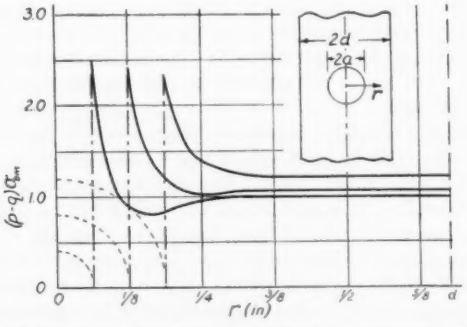

FIG. 7 DIFFERENCE BETWEEN PRINCIPAL BENDING STRESSES ACROSS NET SECTION FOR BENDING STRESS OF UNITY IN GROSS SECTION AWAY FROM HOLE
(Average of results from 1 1/8 × 1/4-in. bakelite plates.)

Partial confirmation of the high stress-concentration factors is found in an exact elastic solution which shows that the concentration factor is the same as for the plane-stress analog (uniaxial tension), i.e., 3, when the thickness of plate is very large compared to the hole diameter. Comparison of Fig. 7 with curves for the uniaxial-tension case and thin-plate bending indicates a much closer correspondence to the tension than the bending, both as to shape of curve and rapidity of falling off of the concentration with distance from the hole. On this basis, the factors of 2.4 and 2.5 for the 1/4- and 1/8-in. holes appear reasonable.

[6] "A Treatise on the Mathematical Theory of Elasticity," fourth edition, by A. E. H. Love, Cambridge University Press, 1927, p. 473.

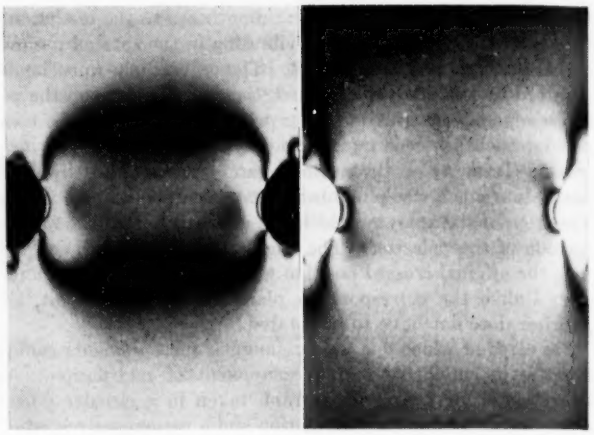

FIG. 8 SEMICIRCULAR NOTCHES IN PLATE UNDER PURE BENDING

Experimental work on semicircular notches, Fig. 8, gives concentration factors based on the gross section that are very nearly the same as for the circular hole. There is no theoretical solution available but reasoning from the corresponding plane-stress cases this result might well be expected.

CONCLUSION

After the initial tension is "frozen" in the plate, the work involved in the proposed method is almost the same as in the photoelastic analysis of a plane-stress problem. The same polariscope is used, and in each case a photograph of the isochromatic pattern is all that is required for most practical problems. If complete information is desired angle measurements must be made. In the analysis of plane stress, both polarizer and analyzer are rotated; in the analysis of plate bending, the polarizer remains fixed and the analyzer alone is rotated. The interpretation of the experimental data is, of course, more involved for bending. Use of Fig. 3 and Equation [7], however, makes the actual work simple.

The stress-concentration factor of 2.4 obtained for the circular hole and semicircular notch, in a plate under pure bending for a diameter equal to the thickness of the plate, is of practical interest. Further work is planned to obtain theoretical stress-concentration factors between the 1.8 for the thin plate and 3 for the small hole.

ACKNOWLEDGMENT

The author is indebted to Prof. R. D. Mindlin of Columbia University for recalling to mind[7] the possibility of the method which was originally used by the author in the equivalent problem of combined tension and torsion. He also wishes to express his thanks to the Sibley School of Mechanical Engineering of Cornell University for making available the facilities of the photoelasticity laboratory, and for a grant from the Westinghouse Research Fund.

An Analytical Method for Determining the Flexibility of Piping Having Two or More Anchorages

By HARRY MILLER,[1] BROOKLYN, N. Y.

Reference is made to an analytical method for determining the flexibility of piping having two anchorages, as developed by H. C. E. Meyer and Prof. W. Hovgaard. This paper is an attempt to amplify the method in such a manner that the flexibility of piping having reverse bends may be conveniently and accurately computed. It is the author's objective also to remove the restriction on the number of anchorages. The mathematical development of the method was suggested in a previous paper by H. Poritsky and H. D. Snively.

Nomenclature

The following nomenclature is used in the paper:

O = origin of co-ordinates; fixed end of pipe

$\vec{i}$ = unit vector along reference X axis

$\vec{j}$ = unit vector along reference Y axis

$\vec{k}$ = unit vector along reference Z axis

$\vec{s}$ = unit vector tangential to pipe element ds

$\vec{r}$ = unit vector radial to pipe element ds

n = unit vector normal to pipe element ds

ρ = radius vector to point P_1, locating pipe element ds in space with respect to X, Y, Z axes

s = length of pipe from O to P_1 measured along pipe axis

F_0 = force reaction at O, due to loads on pipe length s

M_0 = moment reaction at O, due to loads on pipe length s

β = flexibility of pipe element ds

I = moment of inertia of pipe cross section about an axis in plane of cross section and passing through neutral axis of pipe

E = modulus of elasticity in tension

K = flexibility factor for moments normal to plane of an element of curved pipe of radius R

$$K = \frac{12h^2 + 10}{12h^2 + 1}, \quad \text{where } h = \frac{tR}{m^2}$$

t = wall thickness of pipe

m = mean radius of pipe

$[]\cdot[]$ = symbol for vector product

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until January 11, 1943, for publication at a later date. Discussion received after the closing date will be returned.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors and not those of the Society.

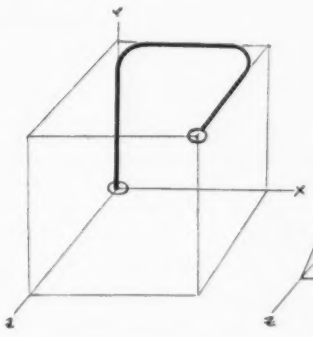

Fig. 1

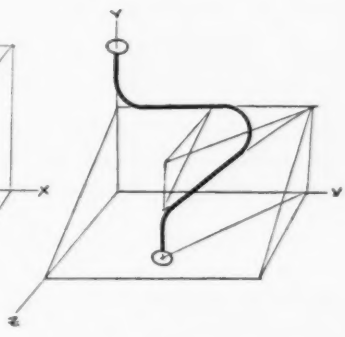

Fig. 2

Introduction

A method for determining analytically the flexibility of piping having two anchorages has been developed by H. C. E. Meyer, and Prof. W. Hovgaard of Gibbs and Cox, Inc., New York, N. Y. This method has been outlined in a paper by S. Noyes.[2] The method is restricted to piping arrangements of the type shown in Fig. 1, and requires that each of the tangent sections and the bends be parallel to at least one of the reference planes X, Y; Y, Z; or Z, X. Furthermore, the piping arrangement cannot have more than two anchorages. It is the purpose of this paper to generalize on this method, in such a manner that piping arrangements of the type shown in Fig. 2 may be conveniently and accurately handled, and also to remove the restriction on number of anchorages.

The mathematical development of this method was suggested in a paper[3] by H. Poritsky and H. D. Snively.

As originally submitted, the paper contained, in addition to the theoretical background of the subject, a series of 36 schedules and tables, which allowed the method to be used in practical problems. Two illustrative problems were offered, one showing the method as applied to a two-anchorage problem and the second as applied to a multianchorage problem. It was felt by the editors that the subject was of too limited interest to warrant publishing the entire paper. Accordingly, the paper was condensed and as herein presented contains only the mathematical development of the subject. For details of the method, as applicable to practical problems, reference may be made to the original paper, which is filed in the Engineering Societies Library, New York, N. Y.

Preliminary Considerations

1 A straight beam, Fig. 3, of length ds, which is subjected to a vector moment M normal to the length, causes the beam to con-

[2] "Thermal Expansion Stresses in Piping," by Mason S. Noyes, *Journal of the American Society of Naval Engineers*, vol. 53, 1941, pp. 275–374.

[3] "Stresses and Deflections of Three-Dimensional Pipe Bends," by H. Poritsky and H. D. Snively, Journal of Applied Mechanics, Trans. A.S.M.E., vol. 62, 1940, p. A-17.

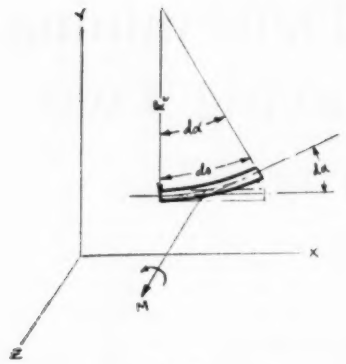

FIG. 3

form to a circle of radius R_e, the plane of R_e and ds also being normal to the vector moment M. The end of the beam rotates through an angle $d\alpha$. From the theory of beams

$$\frac{1}{R_e} = \frac{M}{EI} \quad \ldots\ldots [a]$$

where I is the moment of inertia of the beam cross section about an axis parallel with the vector moment and passing through the neutral axis of the beam, and E is the modulus of elasticity in tension.

$$d\alpha = \frac{ds}{R_e} = \frac{Mds}{EI} \quad \ldots\ldots [b]$$

Thus M/EI can be considered to be the rotation per unit length. It will be denoted by the symbol ψ.

2 If the beam element under consideration is a circular tube and is already bent to a radius R before the application of the vector moment, which is normal to the plane containing R and ds, von Kármán has shown that the rotation per unit length ψ is K times the rotation that would occur if the beam were straight. The "flexibility factor" K is a function of the radius of the bend R, the thickness of the tube, and the diameter of the tube.

3 If the vector moment is parallel to the length ds, the beam is subjected to torsion.

$$\psi = \frac{M}{E_t I_t} \quad \ldots\ldots [c]$$

where E_t is the modulus of elasticity in shear, and I_t is the moment of inertia of the beam cross section about an axis parallel to the length and passing through the neutral axis.

For circular steel pipe

$$E_t = \frac{E}{2.6}$$

$$I_t = 2I$$

$$\psi = \frac{M}{E_t I_t} = \frac{1.3M}{EI} \quad \ldots\ldots [d]$$

Determination of Flexibility of Piping Having Two Anchorages

Refer to Fig. 4

$$\rho = l_x\vec{i} + l_y\vec{j} + l_z\vec{k} \quad \ldots\ldots [1]$$

$$F_0 = P\vec{i} + Q\vec{j} + N\vec{k} \quad \ldots\ldots [2]$$

$$M_0 = M_{0x}\vec{i} + M_{0y}\vec{j} + M_{0z}\vec{k} \quad \ldots\ldots [3]$$

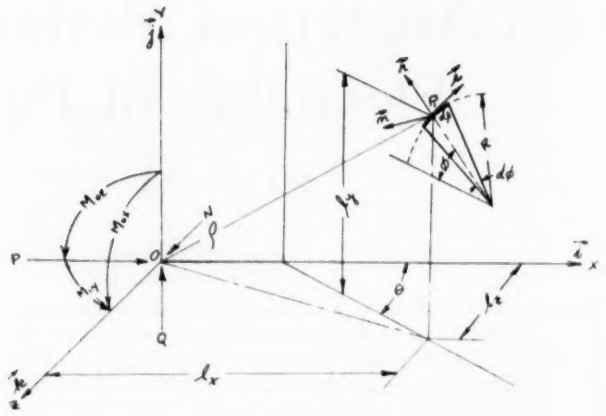

FIG. 4

For circular pipe

$$\beta = \frac{1}{EI}\vec{r} + \frac{1.3}{EI}\vec{s} + \frac{K}{EI}\vec{n} \quad \ldots\ldots [4]$$

$$= \frac{1}{EI}\left\{\vec{r} + \vec{s} + \vec{n}\right\} + \frac{1}{EI}\left\{0.3\vec{s} + (K-1)\vec{n}\right\} \quad \ldots [4a]$$

Let ψ = rotation of pipe per unit length
M = moment at P_1 due to reactions at O

$$\psi = \text{dyad product } [\beta \cdot M] \quad \ldots\ldots [5]$$

$$\left.\begin{aligned} M &= m_x\vec{i} + m_y\vec{j} + m_z\vec{k} \\ &= m_r\vec{r} + m_s\vec{s} + m_n\vec{n} \\ &= M_0 + [F_0 \cdot \rho] \end{aligned}\right\} \quad \ldots\ldots [6]$$

For pipes fixed at both ends and subjected to a thermal expansion $\Delta\epsilon$

$$\Delta\epsilon = \Delta x\vec{i} + \Delta y\vec{j} + \Delta z\vec{k} \quad \ldots\ldots [7]$$

$$\left.\begin{aligned} \int_{s_0}^{s_1} \psi ds &= 0 \\ \int_{s_0}^{s_1} [\psi \cdot \rho] ds &= -\Delta\epsilon \end{aligned}\right\} \quad \ldots\ldots [8]$$

where the integration is carried out from one fixed anchorage to the other.

$$\vec{s} = \cos\theta \sin\phi\,\vec{i} + \cos\phi\,\vec{j} + \sin\phi \sin\theta\,\vec{k} \quad \ldots\ldots [9]$$

$$\vec{n} = -\sin\theta\vec{i} + \cos\theta\vec{k} \quad \ldots\ldots [10]$$

Substitute Equations [9] and [10] in Equation [4a]

$$\beta = \frac{1}{EI} + \frac{1}{EI}\left\{0.3\cos\theta\sin\phi\,\vec{i} + 0.3\cos\phi\,\vec{j} + 0.3\sin\phi\sin\theta\,\vec{k} + (K-1)(-\sin\theta)\vec{i} + (K-1)\cos\theta\,\vec{k}\right\}$$

From Equations [6], [9], and [10], the dyad products

$$m_s \cdot \vec{s} = \cos\theta\sin\phi m_x\vec{i} + \cos\phi m_y\vec{j} + \sin\phi\sin\theta m_z\vec{k}$$

$$m_n \cdot \vec{n} = (-\sin\theta)m_x\vec{i} + \cos\theta m_z\vec{k}$$

$$\psi = \text{dyad product } [\beta \cdot M]$$

$$= \frac{M}{EI} + \frac{1}{EI}\Big\{0.3\cos^2\theta\sin^2\phi m_x\vec{i} + 0.3\cos^2\phi m_y\vec{j} + 0.3\sin^2\phi\sin^2\theta m_z\vec{k} + (K-1)\sin^2\theta m_x\vec{i} + (K-1)\cos^2\theta m_z\vec{k}\Big\}$$

$$= \frac{1}{EI}\Big\{[1 + 0.3\sin^2\phi\cos^2\theta + (K-1)\sin^2\theta]m_x\vec{i} + [1 + 0.3\cos^2\phi]m_y\vec{j} + [1 + 0.3\sin^2\phi\sin^2\theta + (K-1)\cos^2\theta]m_z\vec{k}\Big\} \quad \ldots [11]$$

Equation [6] can be written

$$M = M_0 + [P\vec{i} + Q\vec{j} + N\vec{k}]\cdot[l_x\vec{i} + l_y\vec{j} + l_z\vec{k}]$$
$$= M_0 + (Ql_z - Nl_y)\vec{i} + (Nl_x - Pl_z)\vec{j} + (Pl_y - Ql_x)\vec{k}$$
$$= (M_{0x} + Ql_z - Nl_y)\vec{i} + (M_{0y} + Nl_x - Pl_z)\vec{j} + (M_{0z} + Pl_y - Ql_x)\vec{k}$$

Therefore

$$\left.\begin{aligned} m_x &= M_{0x} + Ql_z - Nl_y \\ m_y &= M_{0y} + Nl_x - Pl_z \\ m_z &= M_{0z} + Pl_y - Ql_x \end{aligned}\right\} \quad \ldots\ldots\ldots [12]$$

Substitute Equations [11] and [12] in [8]

$$\int_{s_0}^{s_1}\psi ds = O = \frac{1}{EI}\int_{s_0}^{s_1}\{M_{0x} + Ql_z - Nl_y\}\{1 + 0.3\cos^2\theta\sin^2\phi + (K-1)\sin^2\theta\}\vec{i}\,ds + \frac{1}{EI}\int_{s_0}^{s_1}\{M_{0y} + Nl_x - Pl_z\}\{1 + 0.3\cos^2\phi\}\vec{j}\,ds + \frac{1}{EI}\int_{s_0}^{s_1}\{M_{0z} + Pl_y - Ql_x\}\{1 + 0.3\sin^2\theta\sin^2\phi + (K-1)\cos^2\theta\}\vec{k}\,ds$$

Therefore

$$\left.\begin{aligned} &\int_{s_0}^{s_1}\{M_{0x} + Ql_z - Nl_y\}\{1 + 0.3\cos^2\theta\sin^2\phi + (K-1)\sin^2\theta\}\,ds = 0 \\ &\int_{s_0}^{s_1}\{M_{0y} + Nl_x - Pl_z\}\{1 + 0.3\cos^2\phi\}\,ds = 0 \\ &\int_{s_0}^{s_1}\{M_{0z} + Pl_y - Ql_x\}\{1 + 0.3\sin^2\theta\sin^2\phi + (K-1)\cos^2\theta\}\,ds = 0 \end{aligned}\right\} \quad \ldots [13]$$

$$-EI\,\Delta\epsilon = \int_{s_0}^{s_1}[m_x\{1 + 0.3\sin^2\phi\cos^2\theta + (K-1)\sin^2\theta\}\vec{i} + m_y\{1 + 0.3\cos^2\phi\}\vec{j} + m_z\{1 + 0.3\sin^2\phi\sin^2\theta + (K-1)\cos^2\theta\}\vec{k}]\cdot[l_x\vec{i} + l_y\vec{j} + l_z\vec{k}]\,ds$$
$$= \int_{s_0}^{s_1}\{[1 + 0.3\cos^2\phi]l_xm_y - [1 + 0.3\sin^2\phi\sin^2\theta + (K-1)\cos^2\theta]l_ym_z\}\vec{i}\,ds + \int_{s_0}^{s_1}\{[1 + 0.3\sin^2\phi\sin^2\theta + (K-1)\cos^2\theta]l_zm_x - [1 + 0.3\sin^2\phi\cos^2\theta + (K-1)\sin^2\theta]l_xm_z\}\vec{j}\,ds + \int_{s_0}^{s_1}\{[1 + 0.3\sin^2\phi\cos^2\theta + (K-1)\sin^2\theta]l_ym_x - [1 + 0.3\cos^2\phi]l_xm_y\}\vec{k}\,ds$$

Therefore

$$\left.\begin{aligned} -EI\,\Delta x &= \int_{s_0}^{s_1}\{M_{0y} + Nl_x - Pl_z\}\{1 + 0.3\cos^2\phi\}\,l_z ds - \int_{s_0}^{s_1}\{M_{0z} + Pl_y - Ql_x\}\{1 + 0.3\sin^2\phi\sin^2\theta + (K-1)\cos^2\theta\}\,l_y ds \\ -EI\,\Delta y &= \int_{s_0}^{s_1}\{M_{0z} + Pl_y - Ql_x\}\{1 + 0.3\sin^2\phi\sin^2\theta + (K-1)\cos^2\theta\}\,l_x ds - \int_{s_0}^{s_1}\{M_{0x} + Ql_z - Nl_y\}\{1 + 0.3\sin^2\phi\cos^2\theta + (K-1)\sin^2\theta\}\,l_z ds \\ -EI\,\Delta z &= \int_{s_0}^{s_1}\{M_{0x} + Ql_z - Nl_y\}\{1 + 0.3\sin^2\phi\cos^2\theta + (K-1)\sin^2\theta\}\,l_y ds - \int_{s_0}^{s_1}\{M_{0y} + Nl_x - Pl_z\}\{1 + 0.3\cos^2\phi\}\,l_x ds \end{aligned}\right\} \quad \ldots [14]$$

Let

$$A_z = \int_{s_0}^{s_1}\{1 + 0.3\sin^2\theta\sin^2\phi + (K-1)\cos^2\theta\}ds$$
$$A_x = \int_{s_0}^{s_1}\{1 + 0.3\sin^2\theta\sin^2\phi + (K-1)\cos^2\theta\}l_x ds$$
$$A_y = \int_{s_0}^{s_1}\{1 + 0.3\sin^2\theta\sin^2\phi + (K-1)\cos^2\theta\}l_y ds$$
$$A_{x^2} = \int_{s_0}^{s_1}\{1 + 0.3\sin^2\theta\sin^2\phi + (K-1)\cos^2\theta\}l_x^2 ds$$
$$A_{y^2} = \int_{s_0}^{s_1}\{1 + 0.3\sin^2\theta\sin^2\phi + (K-1)\cos^2\theta\}l_y^2 ds$$
$$A_{xy} = \int_{s_0}^{s_1}\{1 + 0.3\sin^2\theta\sin^2\phi + (K-1)\cos^2\theta\}l_x l_y ds$$
$$B_z = \int_{s_0}^{s_1}\{1 + 0.3\cos^2\theta\sin^2\phi + (K-1)\sin^2\theta\}ds$$
$$B_y = \int_{s_0}^{s_1}\{1 + 0.3\cos^2\theta\sin^2\phi + (K-1)\sin^2\theta\}\,l_y ds$$
$$B_x = \int_{s_0}^{s_1}\{1 + 0.3\cos^2\theta\sin^2\phi + (K-1)\sin^2\theta\}l_x ds$$
$$B_{y^2} = \int_{s_0}^{s_1}\{1 + 0.3\cos^2\theta\sin^2\phi + (K-1)\sin^2\theta\}l_y^2 ds$$
$$B_{x^2} = \int_{s_0}^{s_1}\{1 + 0.3\cos^2\theta\sin^2\phi + (K-1)\sin^2\theta\}l_x^2 ds$$
$$B_{yx} = \int_{s_0}^{s_1}\{1 + 0.3\cos^2\theta\sin^2\phi + (K-1)\sin^2\theta\}l_y l_x ds$$
$$C_z = \int_{s_0}^{s_1}\{1 + 0.3\cos^2\phi\}ds$$
$$C_x = \int_{s_0}^{s_1}\{1 + 0.3\cos^2\phi\}l_x ds$$
$$C_x = \int_{s_0}^{s_1}\{1 + 0.3\cos^2\phi\}l_x ds$$
$$C_{x^2} = \int_{s_0}^{s_1}\{1 + 0.3\cos^2\phi\}l_x^2 ds$$
$$C_{x^2} = \int_{s_0}^{s_1}\{1 + 0.3\cos^2\phi\}l_x^2 ds$$
$$C_{xx} = \int_{s_0}^{s_1}\{1 + 0.3\cos^2\phi\}l_x l_x ds$$

It is to be noted that the integrations are along the pipe and extend from one anchorage to the other anchorage.

Equations [13] and [14] can now be written

$$\left.\begin{aligned} B_xM_{0z} + B_xQ - B_yN &= 0 \\ C_xM_{0y} + C_xN - C_xP &= 0 \\ A_xM_{0x} + A_yP - A_xQ &= 0 \end{aligned}\right\} \quad \ldots\ldots\ldots [13a]$$

FIG. 6 (*continued*)

An inspection of the six simultaneous Equations, [13*a*] and [14*a*], which determine the end reactions, will show that they are relatively simple, once the A, B, and C coefficients have been determined. In order to simplify the determination of these coefficients, a series of 36 schedules have been drawn up which will handle the 36 most commonly recurring forms of pipe sections. For these cases, the general forms of the integrals have been determined as have their values for limits ranging between 0 and 90 deg at 15-deg intervals. As mentioned in the introduction to this paper, it is these schedules which have been omitted in this condensed paper.

Determination of Flexibility of Piping Having More Than Two Anchorages

Consider Fig. 5, which is shown in single plane. The method to be described is also applicable to piping systems in three dimensions. Some modification of the previous nomenclature is required as follows. The anchorages are labeled successively 1, 2, 3, . . . , etc., through n. The reactions at each anchorage are labeled ${}_1M_{0x}$, ${}_1M_{0y}$, ${}_1M_{0z}$, P_1, Q_1, N_1, ${}_2M_{0x}$, ${}_2M_{0y}$, . . . , etc. The coefficients ${}_1A_x$, ${}_1A_z$, ${}_1A_y$, ${}_1B_x$, . . . , etc., are integrations for the various branches, each considered separately. Let us

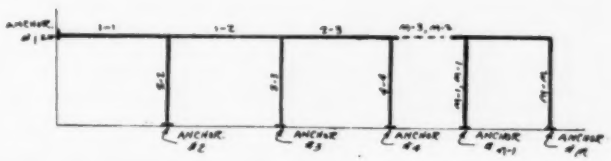

FIG. 5

return now to Equations [13*a*] and [14*a*]. They were derived from Equations [7] and [8]. It will be remembered that the integrations were carried out from one anchorage to the other. Where there are only two anchorages, the reactions at one anchorage are transmitted to the other anchorage through the medium of the connecting pipe and are constant. In the case where there are more than two anchorages, the reactions on the various branches are different. The integrations must thus be subdivided to correspond with the individual branches in which the reactions are constant but different from that of any other branch. Recognizing this, Equations [7] and [8] are modified as follows:

As regards rotations

$$
\left.
\begin{aligned}
&{}_{11}A_x({}_1M_{0x}) + {}_{11}A_y(P_1) - {}_{11}A_z(Q_1) = {}_{22}A_x({}_2M_{0x}) + {}_{22}A_y(P_2) - {}_{22}A_z(Q_2)\\
&{}_{11}A_x({}_1M_{0x}) + \ldots + {}_{12}A_x({}_1M_{0x} + {}_2M_{0x}) + \ldots + = {}_{33}A_x({}_3M_{0x}) + \ldots\\
&{}_{11}A_x({}_1M_{0x}) + \ldots + {}_{12}A_x({}_1M_{0x} + {}_2M_{0x}) + \ldots + {}_{23}A_x({}_1M_{0x} + {}_2M_{0x} + {}_3M_{0x}) = {}_{44}A_x({}_4M_{0x}) + \ldots\\
&\ldots\ldots\ldots

Buckling of Rectangular Plates With Built-In Edges

By SAMUEL LEVY,[1] WASHINGTON, D. C.

This paper presents an exact solution in terms of infinite series of the problem of buckling by compressive forces in one direction of a rectangular plate with built-in edges (zero slope, zero displacement in the direction normal to the plane of the plate). The buckling load is calculated for 14 ratios of length to width, ranging in steps of 0.25 from 0.75 to 4. On the basis of convergence, as the number of terms used in the infinite series is increased, it is estimated that the possible error in the numerical results presented is of the order of 0.1 per cent. A comparison is given with the work of other authors.

Introduction

IN THE design of thin plates buckled by compressive forces in their plane, the degree to which the edges are restrained has an appreciable effect on the buckling load. Approximate values of the buckling stress for a built-in rectangular plate, loaded by compressive stresses in one direction, have been computed by Faxén (1);[2] Sezawa and Watanabe (2); and Maulbetsch (3). The "built-in" edge condition is here defined as zero slope and zero displacement in the direction normal to the plane of the plate. The similar problem of a built-in square plate loaded by equal compressive stresses in two directions has been solved by Taylor (4) and Trefftz (5).

Faxén (1) solves the differential equation $\frac{\partial^4 w}{\partial x^4} + 2\frac{\partial^4 w}{\partial x^2 \partial y^2} + \frac{\partial^4 w}{\partial y^4} = \frac{-h\sigma_x}{D}\frac{\partial^2 w}{\partial x^2}$ (w = displacement normal to the plane of the plate), and gets an infinite set of simultaneous linear equations which must be satisfied in order to satisfy the boundary conditions. He obtains numerical solutions which satisfy up to six of these equations simultaneously. His results are given in the third column of Table 1.

Sezawa and Watanabe (2) solve the differential equation and expand the resulting hyperbolic and circular functions in trigonometric series, deriving an infinite set of simultaneous linear equations. They limit themselves to the first six of these equations in their numerical work. Their results are given in the fourth column of Table 1. They agree closely with Faxén's values.

Maulbetsch (3) extends Faxén's solution of the differential equation up to length-to-width ratios of $a/b = 4$. He obtains numerical solutions which satisfy up to six of the infinite set of simultaneous equations. The results are given in the fifth column of Table 1. Maulbetsch also solves the problem using the Ritz energy method and approximating the deflection surface by the normal modes of vibration of a bar clamped at both ends. He limits his numerical work with this method by requiring the lateral deflection along lines transverse to the direction of loading to be the same as the first normal mode of vibration of a bar clamped at both ends, and by allowing only up to three variations in the lateral deflection along lines parallel to the load. The results are given in the sixth column of Table 1.

The critical stresses obtained by the energy method are seen to be consistently higher than those obtained from an approximate solution of the differential equation. This is to be expected since the energy method generally gives an upper limit of buckling stresses, while the failure to fulfill all boundary conditions for built-in edges is equivalent to relaxing the end restraint and consequently should lead to a lower limit for buckling stresses. The differences between the upper and lower limits exceed 10 per cent in one case ($a/b = 0.75$), and they are of the order of 5 per cent in most cases. It appeared desirable therefore to investigate the possibility of obtaining more accurate values by an exact solution of the differential equation. The results of such an investigation are given in this paper.

Fundamental Equations

Nomenclature. Consider an initially flat rectangular plate of uniform thickness Fig. 1, and let

a = length in direction of load
b = width perpendicular to load
h = thickness
x, y, z = co-ordinate axes with origin at one corner of plate
w = displacement in direction of z axis normal to plane of plate
σ_x = stress in direction of load
$(\sigma_x)_{cr}$ = critical stress for buckling
D = flexural rigidity of plate $= Eh^3/12(1 - \mu^2)$
m_x = moment per unit length at edge $y = 0$
m_y = moment per unit length at edge $x = 0$
k_m = coefficient in expansion of m_x
l_n = coefficient in expansion of m_y
K = symbol in summation formulas

Deflection of Simply Supported Plate Under Combined Edge Moments and Axial Compression in One Direction. The plate with built-in edges may be regarded as a simply supported plate

[1] National Bureau of Standards, U. S. Department of Commerce.

[2] Numbers in parentheses refer to the Bibliography at the end of the paper.

Presented at the National Meeting of the Applied Mechanics Division, Cambridge, Mass., June 19–20, 1942, of The American Society of Mechanical Engineers.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until January 11, 1943, for publication at a later date. Discussion received after the closing date will be returned.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors and not those of the Society.

in which the slope along the edges is made equal to zero by suitably distributed edge bending moments. As a first step toward the solution of the problem we will therefore consider the lateral deflection of a simply supported plate under combined edge moments and axial compression in one direction.

This problem may be examined by substituting for the edge

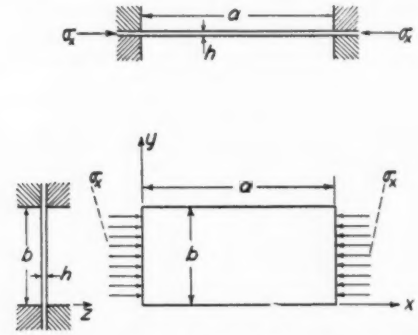

FIG. 1 FLAT RECTANGULAR PLATE WITH ALL EDGES BUILT-IN, LOADED BY UNIFORM COMPRESSION IN ONE DIRECTION

moments an equivalent pressure distribution. Timoshenko[3] has shown that if the lateral displacement is described by the trigonometric series

$$w = \sum_{m=1}^{\infty}\sum_{n=1}^{\infty} a_{m,n} \sin\frac{m\pi x}{a} \sin\frac{n\pi y}{b} \quad \ldots\ldots [1]$$

a concentrated force Q acting at a point (x, y) will be in equilibrium so long as

$$a_{m,n} = \frac{4Q \sin\frac{m\pi x}{a} \sin\frac{n\pi y}{b}}{abD\pi^4 \left\{\left[\left(\frac{m}{a}\right)^2 + \left(\frac{n}{b}\right)^2\right]^2 - \frac{m^2\sigma_x h}{\pi^2 a^2 D}\right\}} \quad \ldots\ldots [2]$$

The edge bending moment along an increment dx or dy of the edge may, on the basis of Saint Venant's principle, be considered equivalent to a couple consisting of a force dQ acting at a short distance c from the edge and a reaction $-dQ$ acting at the edge.

If we define as m_x and m_y the bending moments along those edges of the plate corresponding to the x and y axes, respectively, the value of dQ along these edges is, when $y = 0$

$$dQ = (1/c)m_x\, dx \quad \ldots\ldots [3a]$$

and when $x = 0$

$$dQ = (1/c)m_y\, dy \quad \ldots\ldots [3b]$$

The mode for the minimum buckling load always has a single half wave (n always odd) in the direction perpendicular to the load. The moment at the edge $y = b$ is, therefore, the same as that at $y = 0$ or, when $y = b$

$$dQ = (1/c)m_x\, dx \quad \ldots\ldots [3c]$$

The mode for the minimum buckling load may have either an odd (all values of m odd) or an even (all values of m even) number of half waves in the direction parallel with the load. If the number is odd the moments at the edges $x = 0$, $x = a$ will be equal or, when $x = a$ (m, odd)

$$dQ = (1/c)m_y\, dy \quad \ldots\ldots [3d]$$

[3] Reference (6), p. 317.

while, if the number is even the moments at the edges $x = 0$, $x = a$ will be of opposite sign or, when $x = a$ (m, even)

$$dQ = -(1/c)m_y\, dy \quad \ldots\ldots [3e]$$

The edge moments m_x and m_y may be expressed as trigonometric series with undetermined coefficients. Let

$$\left.\begin{aligned} m_x &= \frac{b^2}{4\pi} \sum_{m=1,2,3\ldots}^{\infty} k_m \sin\frac{m\pi x}{a} \\ m_y &= \frac{a^2}{4\pi} \sum_{n=1,3,\ldots}^{\infty} l_n \sin\frac{n\pi y}{b} \end{aligned}\right\} \quad \ldots\ldots [4]$$

Substituting Equations [4] and [3] in [2], integrating around the edge of the plate, and taking the limit as c approaches zero

$$a_{m,n} = \frac{nk_m + ml_n}{\pi^4 D\left[\left(\frac{m}{a}\right)^2 + \left(\frac{n}{b}\right)^2\right]^2 - \frac{\pi^2 m^2 \sigma_x h}{a^2}} \quad \ldots\ldots [5]$$

where n must always have odd values, and where the values of m must either be all odd or all even.

The lateral deflection is obtained by substituting Equation [5] into Equation [1]

$$w = \sum_{\substack{m=1,3,5\ldots \\ \text{or } 2,4,6\ldots}}^{\infty} \sum_{n=1,3,5\ldots}^{\infty} \frac{(nk_m + ml_n) \sin\frac{m\pi x}{a} \sin\frac{n\pi y}{b}}{\pi^4 D\left[\left(\frac{m}{a}\right)^2 + \left(\frac{n}{b}\right)^2\right]^2 - \frac{m^2\pi^2\sigma_x h}{a^2}} \quad \ldots [6]$$

where m has odd values from 1 to ∞ for buckling into an odd number of waves and even values from 2 to ∞ for buckling into an even number of waves.

Condition of Zero Slope at Built-In Edges. In Equation [6], we have a solution for the lateral deflection of a plate with simply supported edges under combined axial compression in one direction in its plane and moments on its edges. We will now adjust the undetermined coefficients k_m and l_n in the moment Equations [4] in such a way that the slope at the edges of the plate is zero. From Equation [6], setting the slope equal to zero

$$\left.\begin{aligned} 0 = \left(\frac{\partial w}{\partial x}\right)_{x=0,a} &= \sum_{m}^{\infty}\sum_{n}^{\infty} \frac{m\pi}{a} (-1)^m \\ &\frac{(nk_m + ml_n) \sin\frac{n\pi y}{b}}{\pi^4 D\left[\left(\frac{m}{a}\right)^2 + \left(\frac{n}{b}\right)^2\right]^2 - \frac{\pi^2 m^2 \sigma_x h}{a^2}} \\ 0 = \left(\frac{\partial w}{\partial y}\right)_{y=0,b} &= \sum_{m}^{\infty}\sum_{n}^{\infty} -\frac{n\pi}{b} \\ &\frac{(nk_m + ml_n) \sin\frac{m\pi x}{a}}{\pi^4 D\left[\left(\frac{m}{a}\right)^2 + \left(\frac{n}{b}\right)^2\right]^2 - \frac{\pi^2 m^2 \sigma_x h}{a^2}} \end{aligned}\right\} \quad \ldots [7]$$

In order to satisfy Equations [7] for all values of x and y, the coefficients of $\sin \frac{n\pi y}{b}$ and $\sin \frac{m\pi x}{a}$ must separately be zero. This leads to the doubly infinite sets of equations

$$\left.\begin{aligned} 0 &= \sum_{\substack{m=1,3,5\ldots \\ \text{or } 2,4,6\ldots}}^{\infty} \frac{mnk_m + m^2 t_n}{\left[m^2\frac{b^2}{a^2} + n^2\right]^2 - \frac{\sigma_x b^2 h}{\pi^2 D}\frac{m^2 b^2}{a^2}}, \quad (n = 1, 3, 5\ldots) \\ 0 &= \sum_{n=1,3,5\ldots}^{\infty} \frac{n^2 k_m + nmt_n}{\left[m^2\frac{b^2}{a^2} + n^2\right]^2 - \frac{\sigma_x b^2 h}{\pi^2 D}\frac{m^2 b^2}{a^2}}, \quad \begin{pmatrix} m = 1, 3, 5\ldots \\ \text{or } 2, 4, 6\ldots\ldots \end{pmatrix} \end{aligned}\right\} \ldots [8]$$

Solution

Condition for Buckling. In order to satisfy Equations [8], it is necessary either that k_m and t_n be zero (in which case there are no bending moments at the edges and no lateral displacement of the plate), or that σ_x have a value $(\sigma_x)_{cr}$ such that the determinant of the coefficients of k_m and t_n be zero. The smallest value of $(\sigma_x)_{cr}$ is then the desired critical buckling stress.

Summation Formulas. In making the computations it was found convenient to develop certain summation formulas. The method used is described by Guillemin[4] and is credited by him to A. Sommerfeld. These formulas are

$$\sum_{r=1,3\ldots}^{\infty} \frac{n^2}{\left[\frac{m^2b^2}{a^2} + n^2\right]^2 - K\frac{m^2b^2}{a^2}} = \frac{a/b}{4m\sqrt{K}}\left[\frac{\pi}{2}\sqrt{\frac{m^2b^2}{a^2} + \frac{mb}{a}\sqrt{K}}\tanh\frac{\pi}{2}\sqrt{\frac{m^2b^2}{a^2} + \frac{mb}{a}\sqrt{K}} - \frac{\pi}{2}\sqrt{\frac{m^2b^2}{a^2} - \frac{mb}{a}\sqrt{K}}\tanh\frac{\pi}{2}\sqrt{\frac{m^2b^2}{a^2} - \frac{mb}{a}\sqrt{K}}\right] \ldots [9]$$

$$\sum_{m=1,3\ldots}^{\infty} \frac{m^2}{\left[\frac{m^2b^2}{a^2} + n^2\right]^2 - K\frac{m^2b^2}{a^2}} = \frac{a^2/b^2}{2K\sqrt{1-\frac{4n^2}{K}}}\left[\frac{\pi an}{2b}\sqrt{1-\frac{K}{2n^2}\left(1-\sqrt{1-\frac{4n^2}{K}}\right)}\tanh\frac{\pi an}{2b}\sqrt{1-\frac{K}{2n^2}\left(1-\sqrt{1-\frac{4n^2}{K}}\right)} - \frac{\pi an}{2b}\sqrt{1-\frac{K}{2n^2}\left(1+\sqrt{1-\frac{4n^2}{K}}\right)}\tanh\frac{\pi an}{2b}\sqrt{1-\frac{K}{2n^2}\left(1+\sqrt{1-\frac{4n^2}{K}}\right)}\right] \ldots [10]$$

[4] Reference (7), p. 416.

$$\sum_{m=2,4,6\ldots}^{\infty} \frac{m^2}{\left[\frac{m^2b^2}{a^2} + n^2\right]^2 - K\frac{m^2b^2}{a^2}} = \frac{a^2/b^2}{2K\sqrt{1-\frac{4n^2}{K}}}\left[\frac{\pi an}{2b}\sqrt{1-\frac{K}{2n^2}\left(1-\sqrt{1-\frac{4n^2}{K}}\right)}\coth\frac{\pi an}{2b}\sqrt{1-\frac{K}{2n^2}\left(1-\sqrt{1-\frac{4n^2}{K}}\right)} - \frac{\pi an}{2b}\sqrt{1-\frac{K}{2n^2}\left(1+\sqrt{1-\frac{4n^2}{K}}\right)}\coth\frac{\pi an}{2b}\sqrt{1-\frac{K}{2n^2}\left(1+\sqrt{1-\frac{4n^2}{K}}\right)}\right] \ldots [11]$$

Convergence. The critical stress $(\sigma_x)_{cr}$ was computed by taking a sufficient number of terms in the determinant of the coefficients of k_m and t_n in Equations [8] so that the value of $(\sigma_x)_{cr}$ remained unchanged after taking additional terms.

Fortunately the convergence is rapid. For example, for the case of a square plate ($a = b$) the approximate value of $(\sigma_x)_{cr}$ which reduces the determinant involving t_1, k_1, k_3, k_5, and k_7 to zero is 10.047 (π^2D/b^2h); the approximate value of $(\sigma_x)_{cr}$ which reduces the determinant involving t_1, t_3, and k_1 to k_{13} to zero is 10.073 (π^2D/b^2h); the approximate value $(\sigma_x)_{cr}$ which reduces the determinant involving t_1 to t_5 and k_1 to k_{23} to zero is 10.074 (π^2D/b^2h); and the approximate value $(\sigma_x)_{cr}$ which reduces the determinant involving t_1 to t_7 and k_1 to k_{31} to zero is also 10.074 (π^2D/b^2h). Similar rapid convergence is indicated in Table 1 for ratios of length to width of 1.75, 2.5, 3.5, and 4. On the basis of these extensive computations, it seems reasonable to assume that, for length-to-width ratios up to 4, the approximate value of $(\sigma_x)_{cr}$ which reduces the determinant involving t_1, t_3, and k_1 to k_{13} to zero differs less than 0.1 per cent from the exact value of $(\sigma_x)_{cr}$ (which reduces the infinite determinant to zero).

Results. The results of the computation of the approximate values of $(\sigma_x)_{cr}$ which reduce finite determinants of the coefficients of k_m and t_n in Equations [8] to zero together with the estimated value (based on the convergence) of $(\sigma_x)_{cr}$ which would reduce the infinite determinant to zero are given in Table 2 for ratios of length to width from 0.75 to 4.

The results are plotted in Fig. 2. It is evident that as the ratio of length to width increases, the value of the critical stress approaches 6.97 (π^2D/b^2h), the value given by Dunn (8) for the critical stress for an infinitely long plate simply supported on the loaded edges and built-in on the other two edges. It is also evident that as the ratio of length to width approaches zero the

value of the critical stress approaches $\frac{4b^2}{a^2}\frac{\pi^2 D}{b^2 h}$, the critical stress for a Euler column with built-in ends.

Comparison With Other Authors. The asymptotic values of critical-stress ratio derived in this paper are repeated in the last column of Table 1 for comparison with the values obtained by previous authors.

Faxén's results agree within about 2 per cent with the results in the present paper and are consistently equal to or lower except for $a/b = 1.75$. For $a/b = 1.75$, he derives a value of 8.18 which is even higher than the upper limit (energy solution) value of 8.17 given by Maulbetsch.

The results of Sezawa and Watanabe are equal to or lower than the results in the present paper by amounts up to about 0.3 per cent.

Maulbetsch has extended Faxén's solution of the differential equation up to values of $a/b = 4$. The results he obtained are consistently lower than the results in the present paper by amounts up to about 6 per cent. Maulbetsch's results using the Ritz energy method agree within about 10 per cent and are consistently higher than the results given in the present paper.

Investigation of Self-Excited Torsional Oscillations and Vibration Damper for Induction-Motor Drives

By A. M. WAHL[1] and E. G. FISCHER,[2] EAST PITTSBURGH, PA.

An unusual case of torsional oscillation was observed recently on several large induction-motor drives used for tunnel ventilation on the Pennsylvania Turnpike. These drives, which consist essentially of an induction motor driving a heavy centrifugal fan through a speed reducer, showed a severe torsional oscillation (with a double amplitude around 80 deg) at a point between two thirds and full speed during the accelerating period. These vibrations were found to be self-excited, as a consequence of the negative damping inherent in the shape of the speed-torque curve of the normal induction motor.

After consideration of various methods for eliminating the trouble, a torsional-vibration damper of relatively simple design was developed. Torsiograph records made on the actual drive showed that the oscillation was reduced to negligible values by the use of this damper.

Since induction-motor drives of this general type are used rather widely, it was felt that an account of this investigation, including the methods of calculating damper capacity, the laboratory tests on the damper, and the field tests on the actual drives would be of value to engineers, particularly those interested in vibration.

Introduction

An unusual case of self-excited torsional oscillation was encountered recently on a large induction-motor drive used for tunnel ventilation on the Pennsylvania Turnpike, as indicated schematically in Fig. 1. The torsional oscillation, which took place only when the drive was coming up to speed, was evidenced by chatter and noise at a point between two thirds and full speed, the noise being due largely to impact caused by torque reversal. The cause of the oscillation was the "negative damping" present as a result of the slope of the speed-torque curve of the motor. Since this type of oscillation is theoretically possible in all normal induction-motor drives (where the rotors are of relatively low resistance), it was felt that an account of the investigation of the vibration together with the results of tests made on the special damper used to control the oscillation, would be of value to engineers, particularly those interested in vibration.

Referring to Fig. 1 the drive consists essentially of a main motor and an auxiliary motor coupled to the high-speed shaft of a speed reducer by means of the couplings D and D'. The

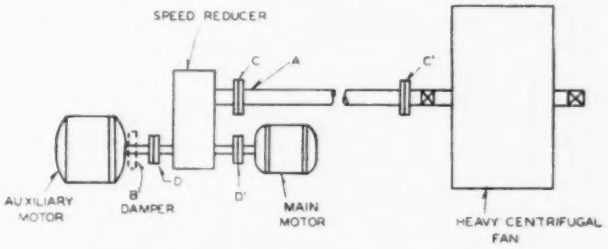

Fig. 1 Sketch of Fan Drive for Tunnel Ventilation (Blue Mt. and Kittatinny Mt. tunnels, Pennsylvania Turnpike.)

Fig. 2 Typical Torsiograph Record of Drive Without Damper

low-speed shaft of the speed reducer (which had a reduction ratio of about 7:1) is coupled to a heavy centrifugal fan through the couplings C and C'. In this case the equivalent inertia of the fan was about 90 times that of the motor while most of the flexibility of the system was in the long shaft between the couplings C and C'. In the drives under consideration, the auxiliary motor had a rating of either 40 or 50 hp; the main motor, $5\frac{1}{2}$ or $7\frac{1}{2}$ hp. The main motor is used most of the time, the auxiliary motor being used only occasionally when maximum speed is required.

To measure the torsional vibration, a Geiger torsiograph was belted to the low-speed shaft at A, Fig. 1. Because of the high inertia of the fan, the node in the system was practically at the fan hub. Thus the vibrograph measures essentially the twist in the shaft between point A and the fan hub. Because of the low acceleration during the starting period (which lasted around 25 to 45 sec for the drives tested), the seismic mass of the vibrograph did not come against the stops except when the vibration reached large amplitudes.

A sketch of a typical vibrograph record obtained during the starting period of these drives is shown in Fig. 2. At the start there is a transient oscillation of small amplitude at the torsional natural frequency of the system. This oscillation is due primarily to the electrical torque suddenly applied to the system and dies out after a few cycles. The torques set up through this transient condition may be calculated using the methods developed by one of the authors;[3] in the present instance such torques are low and of no concern. However, as seen from the torsiograph record, in the range from one half to full speed, a relatively severe oscillation continues to build up until full speed is almost reached after which it dies down.

This phenomenon may be explained as follows: The solid

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until January 11, 1943, for publication at a later date. Discussion received after the closing date will be returned.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors and not those of the Society.

[3] "Transient Torques in Induction-Motor Drives," by A. M. Wahl, Journal of Applied Mechanics, Trans. A.S.M.E., vol. 63, 1941, p. A-17.

line in Fig. 3 represents a typical speed-torque curve of a low-resistance induction motor of the type used for this service. From the curve it may be seen that in the range from *A* to *B* below full speed an increase in speed produces an increase in torque and vice versa. Thus for any small oscillation the alternating component of the torque is in phase with the alternating component of the angular velocity and energy will be put into the system. This condition is equivalent to "negative damping." If the positive damping present in the rest of the system is insufficient to compensate for this negative damping, the oscillation will build up, as shown in Fig. 2. When full speed is approached the slope of the curve is such as to give positive damping, Fig. 3, and this explains why the oscillation dies out near this point.

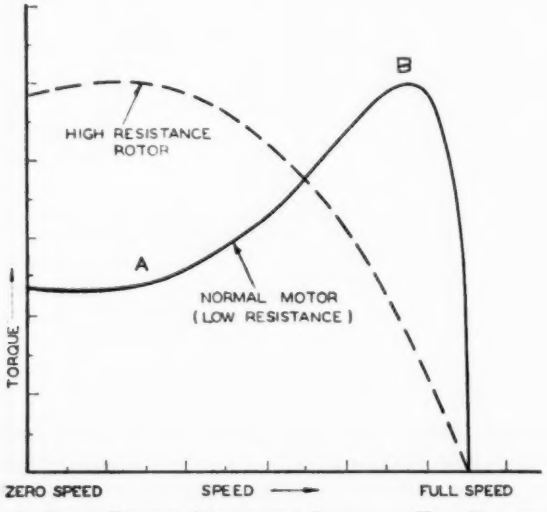

FIG. 3 SPEED-TORQUE CURVES FOR LOW- AND HIGH-RESISTANCE ROTORS

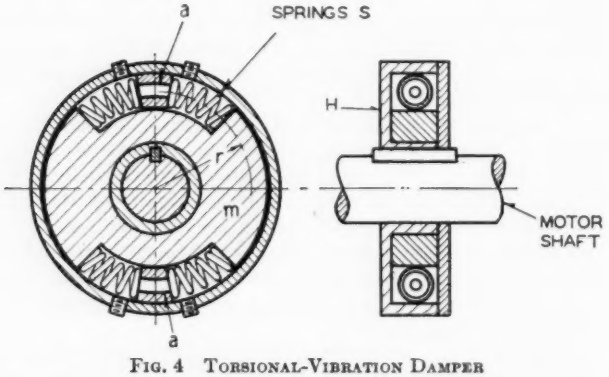

FIG. 4 TORSIONAL-VIBRATION DAMPER

It was considered advisable to eliminate these oscillations not only because of the noise and chatter produced but also because of the possible risk of eventual fatigue failure due to the stresses set up. Consideration was given to several methods for doing this, but all were found to involve certain disadvantages. One method is to use a squirrel-cage rotor of high resistance so that the slope of the speed-torque curve is changed as indicated by the dotted curve of Fig. 3. Here it is seen that during most of the accelerating period, the slope of the curve is such as to give a decrease in torque for an increase in speed, i.e., to give positive damping, in contrast to the normal curve for a low-resistance rotor (shown by the full lines) which yields an increase in torque with an increase in speed. However, a high-resistance rotor has lower efficiency at operating speeds and hence is not permissible. The use of a wound-rotor induction motor would enable a resistance to be inserted in the rotor circuit during the accelerating period and thus obtain a curve similar to the dotted curve of Fig. 3. While this method would give better results at operating speeds than the high-resistance squirrel-cage rotor alone, it involves added expense, and at the same time the efficiency at operating speeds is not as good as that obtained by means of a low-resistance squirrel-cage rotor.

An improvement could also be had by using a double-cage rotor but this does not completely eliminate the objectionable positive slope in the speed-torque curve and hence might not eliminate the trouble. In addition extra expense is involved.

After a consideration of these and other methods it was decided to use the relatively simple tuned vibration damper shown schematically in Fig. 4. This damper is keyed directly to the motor shaft at *B*, Fig. 1. It consists essentially of a mass *m*, mounted in a housing *H*, having an outside diameter of about 12 in. so that it may oscillate torsionally on the springs *S*. These springs are so chosen as to give the damper mass a frequency approximately equal to the lowest torsional natural frequency of the drive. By varying the size of the holes *a*, the amount of damping and shape of the resonance curve may be changed. If a light oil or fluid is used with an orifice of the proper size, the damping force will be proportional to the square of the velocity of flow in the orifice and will be practically independent of viscosity. Hence the damper operation may be made practically independent of temperature changes such as occur in service. As can be noted from Fig. 4, the complete assembly is self-contained and is permanently sealed so as to require practically no attention or maintenance. In addition, close clearances between the mass and housing are not required, thereby avoiding machining difficulties. Since the damper will only operate during the starting period no loss in efficiency during operation is involved by its use.

The object of the present investigation was primarily to obtain data on the energy absorption of the damper, to develop methods of calculation which may be used in the design of similar drives, and to check these methods by actual field tests on the drives. A further object was to obtain data on the actual positive damping present in drives of this type.

1—THEORETICAL ANALYSIS AND LABORATORY TESTS OF DAMPER

THEORY

For purposes of analysis the damper may be represented by the single-degree-of-freedom system shown in Fig. 5, the mass *m*

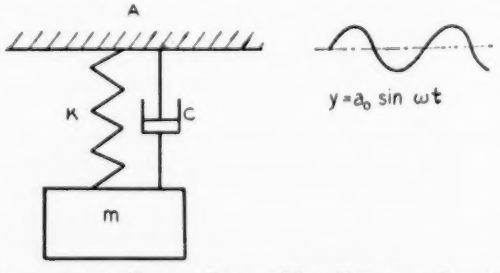

FIG. 5 SINGLE-DEGREE SYSTEM WITH VIBRATING SUPPORT

representing the damper inertia, and the spring constant *k* the torsional spring constant of the mass on the springs. Damping is represented by the dashpot *c*. It is assumed that the support *A* has a sinusoidal vertical motion $y = a_0 \sin \omega t$ which represents the torsional motion of the motor shaft on which the damper is mounted.

If it be assumed that the damping produced by the dashpot c is proportional to the relative velocity between the mass m and the support A, an exact solution of the problem of determining the energy absorption is available.[4] However, in the present instance where the clearances are such that little viscous damping occurs, provided a light oil is used, most of the damping is produced by flow of oil through a fixed orifice; here the damping force is proportional to the relative angular velocity squared. Some additional damping is produced by the rubbing of the mass m, Fig. 4, on its bearing; where a very light oil is used this may be considered as Coulomb damping. It therefore appears reasonable to obtain an approximate solution for this case by assuming a combination of velocity squared and Coulomb damping together with sinusoidal motion. On the basis of equal energy dissipation per cycle, an equivalent viscous-damping factor c is derived. In turn this factor c is used in the known expression for amplitude of motion for the case of viscous damping.[5]

The procedure is as follows:

The known solution for the single-degree system of Fig. 5 with viscous (or first power velocity) damping is

$$\frac{x_0}{a_0} = \frac{\omega^2/\omega_n^2}{\sqrt{\left(1 - \frac{\omega^2}{\omega_n^2}\right)^2 + \left(\frac{c\omega}{m\omega_n^2}\right)^2}} \quad \ldots\ldots [1]$$

where

a_0 = amplitude of motion of support
x_0 = peak amplitude of relative motion between mass and support
c = equivalent damping constant
ω = circular frequency of motion of support
k = spring constant
m = mass
$\omega_n = \sqrt{k/m}$ = undamped natural circular frequency

The equivalent damping constant c is calculated as follows:

Let $x = x_0 \sin \omega t$ be the relative motion between mass and support. Then for viscous damping the energy dissipated per cycle is

$$U = \pi c \omega x_0^2 \quad \ldots\ldots [2]$$

For velocity-squared damping where the damping force is taken as $c_1(\dot{x})^2$ the energy dissipated per cycle will be

$$U_1 = 4\int c_1(\dot{x})^2 dx = 4\int_0^{\pi/2\omega} c_1 x_0^3 \omega^3 \cos^3 \omega t \omega dt = \frac{8}{3} c_1 \omega^2 x_0^3 \quad \ldots\ldots [3]$$

The energy per cycle dissipated by Coulomb damping (which may be represented by a friction force F) is

$$U_2 = 4Fx_0 \quad \ldots\ldots [4]$$

The criterion of equivalent energy dissipation per cycle gives

$$U = U_1 + U_2 \quad \ldots\ldots [5]$$

$$\pi c \omega x_0^2 = \frac{8}{3} c_1 \omega^3 x_0^3 + 4Fx_0 \quad \ldots\ldots [6]$$

or

$$c = \frac{8}{3\pi} c_1 \omega x_0 \left(1 + \frac{3}{2}\frac{F}{c_1 \omega^2 x_0^2}\right) \quad \ldots\ldots [7]$$

Substituting this expression for c in Equation [1], and simplifying we find

$$\lambda = \frac{x_0}{a_0} = \frac{(1 - \tau^2)\sqrt{1 + \gamma_2}}{\sqrt{2}\,\tau^2 \gamma_1} \sqrt{\sqrt{1 + \lambda_1} - 1} \quad \ldots\ldots [8]$$

where λ = magnification of motion.

$$\lambda_1 = \frac{4\tau^2\gamma_1^2}{(1 - \tau^2)^4} \frac{(1 - \gamma_1^2\gamma_2^2/\tau^4)}{(1 + \gamma_2)^2} \quad \ldots\ldots [9]$$

$$\left.\begin{aligned} \tau &= \frac{\omega}{\omega_n} & \gamma_1 &= \frac{8}{3\pi}\frac{c_1 a_0}{m} \\ \gamma_2 &= \frac{3F}{2\omega_n^2 c_1 a_0^2} & \gamma_3 &= \frac{2\tau^2\gamma_1^2\gamma_2}{(1 - \tau^2)^2} \end{aligned}\right\} \quad \ldots\ldots [10]$$

When the forced frequency is equal to the natural frequency, i.e., when $\omega = \omega_n$, Equation [8] reduces to

$$\lambda_r = \sqrt{\frac{1}{\gamma_1} - \gamma_2} \quad \ldots\ldots [11]$$

where λ_r = magnification at $\omega = \omega_n$.

Using these equations in Equation [5], the energy dissipation per cycle becomes

$$U = \frac{8}{3} c_1 \omega^2 a_0^3 \lambda^2 + 4Fa_0\lambda \quad \ldots\ldots [12]$$

To apply these formulas to the damper shown on Fig. 4, the constant k is taken as the torsional spring constant, m as the torsional moment of inertia of the mass, and F as the friction torque. To calculate the constant c_1 which determines the damping torque in the equation

$$T_d = c_1(\dot{x})^2 \quad \ldots\ldots [12a]$$

where $\dot{x}$ in this case is the relative angular velocity between the mass and the housing, the procedure is as follows:

Let v = average velocity of fluid flow through orifice
v_p = velocity of motion at center line of springs at mean radius r (Fig. 4)

Then

$$v = \frac{A_p v_p}{A_h K_d} = \frac{A_p r \dot{x}}{A_h K_d} \quad \ldots\ldots [13]$$

where

A_p = piston area (or sectional area of openings for springs)
A_h = area of orifice
K_d = discharge coefficient

$$v_p = r\dot{x} \quad \ldots\ldots [14]$$

The pressure required to cause this flow is

$$p = \frac{\gamma v^2}{2g} \quad \ldots\ldots [15]$$

where γ is the weight of the oil per unit of volume and g the acceleration of gravity. Using Equation [13] in Equation [15]

$$p = \frac{\gamma}{2g}\left(\frac{A_p}{A_h K_d}\right)^2 r^2(\dot{x})^2 \quad \ldots\ldots [16]$$

Since for this case there are in effect two pistons, using Equation [16], the damping torque becomes

$$T_d = 2pA_p r = \frac{\gamma}{g}\frac{A_p^2}{A_h^2}\frac{r^3}{K_d^2}(\dot{x})^2 \quad \ldots\ldots [17]$$

[4] "Mechanical Vibrations," by J. P. Den Hartog, second edition, McGraw-Hill Book Company, Inc., New York, N. Y., 1940, p. 41.

[5] This method was suggested by L. S. Jacobsen, "Steady Forced Vibration as Influenced by Damping," Trans. A.S.M.E., vol. 52, 1930, paper APM-52-15, pp. 169–181; also, reference (4), p. 407.

from which

$$c_1 = \frac{\gamma}{gK_d^2} \frac{A_p^3 r^2}{A_h^2} \quad \ldots\ldots\ldots\ldots\ldots\ldots [18]$$

Tests on Dampers

As a check on the theory, a series of laboratory tests was made on dampers of two different sizes. The larger one had a mass of $10^3/_4$ in. OD with springs of $1^1/_2$ in. OD, the smaller a mass of $9^3/_4$ in. OD with $1^1/_4$-in. springs. The method of making the test was to mount the damper on a motor shaft (supported on ball bearings to reduce friction) and oscillate it back and forth through a small angle by means of the apparatus shown in Fig. 6.

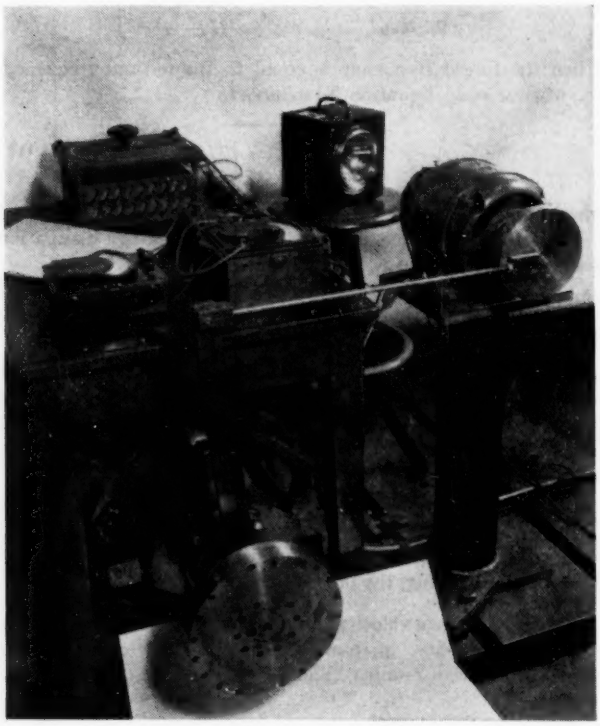

Fig. 6 Damper Test Arrangement

Essentially this consisted of a small 1-hp d-c motor having an eccentric mounted on its shaft. Holes in the eccentric enabled the stroke to be varied, while the frequency of oscillation could be changed by varying the speed of the motor. An accurate check of the frequency was possible by means of the stroboscope shown. In Fig. 7, a view of the test apparatus with the damper disassembled is shown.

The test procedure was as follows: The motor was operated at a constant speed, determined by the stroboscope and readings of armature current I, and voltage and watts were taken. Then the motor was stopped and the connecting rod disconnected from the eccentric. After the motor was started again, readings of the same quantities were taken at the same speed. From both the load and no-load wattage readings the I^2R losses were subtracted; the difference was then due to the energy absorption by the damper since the no-load run would give the losses due to hysteresis, bearing friction, windage, etc. As it was not found feasible to remove the damper from the shaft during the no-load run, a test was made with the damper mass blocked to determine the bearing losses of the damper shaft at various amplitudes and frequencies. These latter were found to be very small compared to the energy absorption of the damper except at points considerably removed from resonance. A further slight correction in the readings was therefore made taking these bearing losses into account.

Tests were made at various frequencies and amplitudes on both the large and the small damper using various sizes of orifices. Dimensions of the orifices used in the tests are shown in Fig. 8. In all cases, the damper was filled with Wemco C oil which is a very light oil having a viscosity of about 14 centipoises (or about 90 sec Saybolt) at room temperature.

The effect of varying the orifice diameter for the large damper is shown in Fig. 9, for frequencies near the resonant value and at a double amplitude of 8 deg (corresponding to a 3-in. stroke at the end of a $21^1/_2$-in. arm). On these curves the energy absorption, calculated from the wattage readings, is plotted against the frequency in cycles per minute. The orifices tested were of $^{13}/_{16}$, $^9/_{16}$, $^7/_{16}$, and $^5/_{16}$ in. diam. The reduction in energy absorption near the resonant frequency is quite pronounced for the smaller orifices. Similar curves for the small damper with orifice diameters of $^{19}/_{32}$, $^7/_{16}$, $^5/_{16}$, and $^3/_{16}$ in. are shown in Fig. 10.

Fig. 7 Damper Completely Disassembled

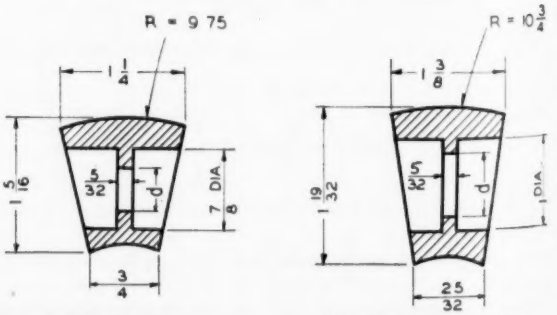

Fig. 8 Orifice Dimensions for Small and Large Dampers

The effect of varying the amplitude of oscillation on the energy absorption per cycle is shown in Figs. 11, 12, and 13, the full lines representing experimental results, the dotted lines the theoretical results (to be discussed later). In Fig. 11, the results on the small damper with the $^{19}/_{32}$-in-diam orifice are shown for double amplitudes of 8 and 5.3 deg. In Fig. 12, similar curves are shown for the large damper with the $^{13}/_{16}$-in. orifice and at the same amplitudes, while, in Fig. 13, the results obtained with this damper at amplitudes of 8 and 10.7 deg using the $^{9}/_{16}$-in. orifice are shown.

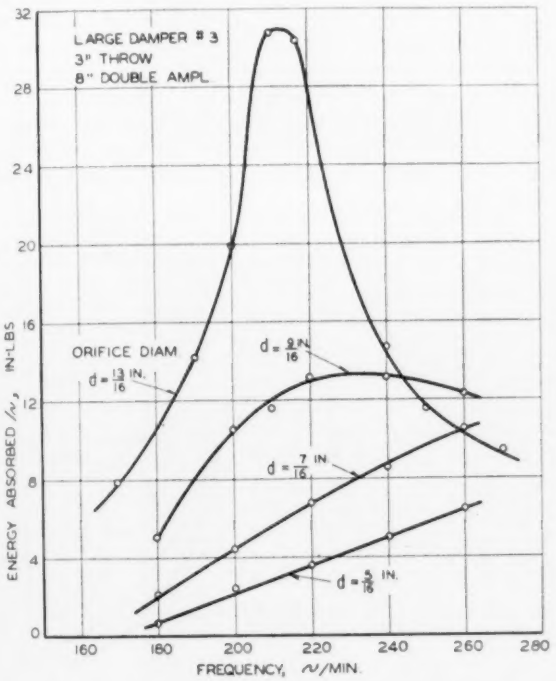

FIG. 9 ENERGY ABSORPTION VERSUS FREQUENCY FOR VARIOUS ORIFICE DIAMETERS, FOR LARGE DAMPER

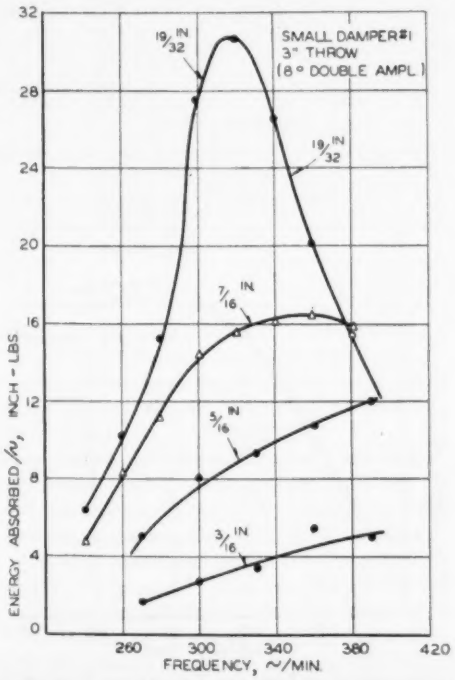

FIG. 10 ENERGY ABSORPTION VERSUS FREQUENCY FOR VARIOUS ORIFICE DIAMETERS, FOR SMALL DAMPER

It is interesting to note that, for the large damper, Fig. 12, using the 2-in. stroke (5.3 deg double amplitude), practically no damping occurred until the frequency reached 200 cycles per min. This may be explained as follows: There is always a slight amount of friction between the mass and its bearing on the housing. Until the amplitude and frequency of oscillation become great enough so that the torsional acceleration is sufficient to overcome this friction, no relative motion between mass and housing and hence no damping will take place. Calculations based on these tests indicate that a static coefficient of friction around 0.3 to 0.4 was present. In actual operation when mounted on a rotating motor shaft instead of a stationary one it may be expected that this coefficient of friction will be less. In the laboratory tests, a lower value may also be expected, except where the energy absorption is practically zero and no appreciable movement of the mass takes place.

This friction effect could be eliminated by mounting the mass on roller or ball bearings. In the present instance, however, this additional complication was not felt worth while, since as will be seen later, the use of the damper reduced the amplitude of oscillation to sufficiently low values

CALCULATION OF ENERGY ABSORPTION OF DAMPER AND COMPARISON WITH TEST

In calculating the energy absorption of the damper from Equation [12], it is necessary to know both the discharge coefficient K_d for the orifice and the friction coefficient μ between the mass m and the housing, Fig. 4. It is known that, for a plate orifice in a tube under steady-state flow conditions, the discharge coefficient will vary considerably depending upon the Reynolds number and on the ratio d/D between the orifice diameter and the tube diameter.[6] In addition the friction coefficient μ may vary considerably. An independent determination of these values for the conditions obtaining in the tests would be difficult. It was therefore felt that a satisfactory method of determining values of K_d and μ for use in calculation would be to assume some reasonable figures and compare the calculated curves obtained with the test curves. On this basis, a coefficient of friction μ = 0.2 and a discharge coefficient K_d = 0.8 were assumed for calculating the $^{9}/_{16}$-in. orifice in the larger damper and the $^{19}/_{32}$- and $^{7}/_{16}$-in. orifices in the smaller damper. Theoretical curves obtained by using these values in Equations [8] and [12] are shown by the dotted curves of Figs. 11, 13, and 14. It may be seen that, within the range covered by the tests, the agreement between test and calculated values may be considered as satisfactory for practical use in view of the approximate nature of the method of calculation.

In the case of the $^{13}/_{16}$-in. orifice in the larger damper, as indicated in Fig. 12, better results were obtained by assuming a discharge coefficient K_d = 0.9. This appears reasonable since, within the range of Reynolds numbers around 300 to 3000, as used in the tests, the value of K_d may be expected to be higher for the larger ratios of d/D; in the case of the $^{13}/_{16}$-in. orifice used on the larger damper, the ratio d/D was approximately 0.8, as compared with ratios of about 0.4 to 0.7 for the other orifices.

The numerical constants used in the calculations were as follows:

[6] For further discussion of this, refer to "Fluid Mechanics for Hydraulic Engineers," by H. Rouse, Engineering Societies Monographs, McGraw-Hill Book Company, Inc., New York, N. Y., 1938, p. 260; also "The Laws of Similarity for Orifice and Nozzle Flows," by J. L. Hodgson, Trans. A.S.M.E., vol. 51, 1929, paper FSP-51-42, pp. 303–332.

	Small damper	Large damper
m =	0.54 lb-in-sec^2	0.917 lb-in-sec^2
ω_n =	32.5 radians per sec	21.5 radians per sec
γ =	0.031 lb per cu in.	0.031 lb per cu in.
A_p =	1.71 sq in.	2.43 sq in.
r =	4.2 in.	4.6 in.
F =	7.7 in-lb	11.8 in-lb

The values of F given correspond to a friction coefficient $\mu = 0.2$ between mass and housing.

2—FIELD TESTS ON INDUCTION-MOTOR DRIVES

Torsiograph Tests With and Without Damper

As mentioned previously, tests were made by driving a Geiger torsiograph through a belt attached to the low-speed shaft at A, Fig. 1. (A photograph of one of the drives tested showing the damper A, the motors, and the speed reducer is shown in Fig. 15.) Besides the torsiograph records, speed and voltage readings were also taken so that the amplitude of oscillation as obtained from the torsiograph records could be correlated with motor speed.

Typical records obtained on three different units with the damper removed or blocked (so as to be inoperative) are shown on the records marked WB-1, WB-2, and EK-2 in Fig. 16. The records obtained for the same units with the damper on are also indicated; the improvement effected by using the damper is shown by comparison. In most cases the amplitude of oscillation without the damper was sufficient to cause the vibrograph pulley to strike the stops; this corresponds to an amplitude of about 12 deg at the low-speed shaft (or roughly 85 deg at the high-

(Damper shown at *A*.)

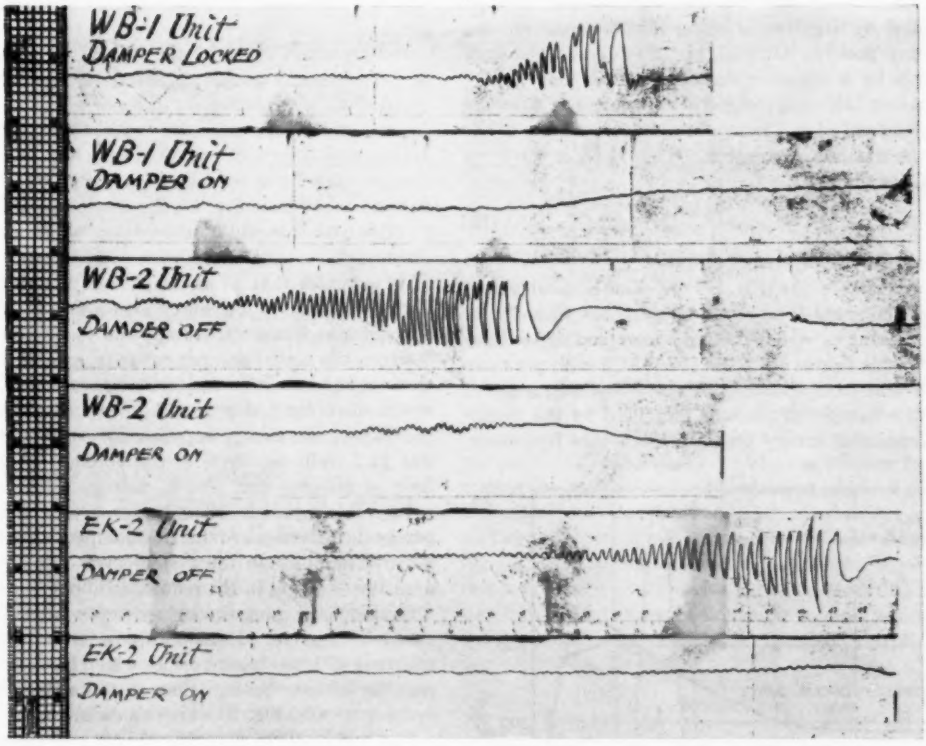

FIG. 16 TORSIOGRAPH RECORDS ON SEVERAL UNITS WITH AND WITHOUT DAMPER
(Scale, 0.085 in. = 1 deg at low-speed shaft.)

speed shaft). By using the damper, the double amplitude was reduced to less than 1 deg at the low-speed shaft, a value which is negligible from a stress standpoint. The natural frequency of oscillation for the units tested was about 5.8 cycles per sec for the smaller ones and 3.8 for the larger.

A typical curve of double amplitude of oscillation at the low-speed shaft versus speed, as determined from the torsiograph records and tachometer readings taken before the installation of the dampers, is shown together with the speed-torque curve in Fig. 17. It will be noted that during the first part of the accelerating period where the speed is low, no appreciable oscillation is present. The reason for this is that the slope of the speed-torque curve is less at the lower speeds, hence the negative damping at these speeds is not sufficiently great to overcome the positive damping in the system. As the speed increases, however, the slope increases and finally a point is reached where the negative damping sufficiently exceeds the positive damping in the system so that a rapid build-up of the oscillation may occur. After reaching a maximum amplitude the oscillations die out since, as mentioned before, the slope of the speed-torque curve is such as to give positive damping near full speed.

For comparison with the test results the dashed curve of Fig. 17 has been computed from the slope of the speed-torque curve by assuming that the positive damping in the system was equal to $^1/_2$ the negative damping supplied by the motor.[7] This was done by taking the amplitude equal to $Ae^{c_d t/2I}$ where c_d is the net damping constant, I the moment of inertia of the motor rotor, and A

[7] Further studies, based on the electrical characteristics of the motor, indicate that the negative damping may be determined with sufficient accuracy from the slope of the speed-torque curve, where the frequency of oscillation is low compared to the electrical-supply frequency as it was in the present case.

the initial amplitude.[8] It is seen that this assumption yields good agreement with the test curve; however, close agreement between test and theory in this case should not be expected since the positive damping in the system was not known with any great degree of accuracy.

From the records of Fig. 16 it may be seen that even with the damper in place there is still a small amplitude of oscillation. The explanation for this may be found in the slight friction existing between the damper mass and the housing. In order for the damper to function, the amplitude of oscillation must rise to a high enough value so that the acceleration is sufficient to overcome this friction and allow relative motion to take place. The variations in the amplitudes of motion with the damper in place may probably be ascribed primarily to variations in the positive damping present in the different units.

In order for the damper to be effective at any amplitude and frequency of motion the energy dissipated by the damper, as given by Equation [12] (or Figs. 9 to 14), must be greater than the energy supplied by negative damping at this amplitude and frequency, less any positive damping in the system. The work supplied per cycle by a negative damping torque may be obtained from Equation [2], using instead of c the negative damping constant c_0, and instead of x_0 the amplitude of motion a_0 of the shaft on which the damper is mounted. Thus if U_n is the work supplied by negative damping

$$U_n = \pi c_0 \omega a_0^2 \ldots\ldots\ldots\ldots\ldots\ldots [19]$$

where ω is the angular frequency of oscillation.

For the smaller (WB-1) units (Fig. 17) the value of c_0 calculated from the slope of the speed-torque curve was about 40 in-lb per radian per sec. Taking $a_0 = 0.07$ radian corresponding to 8-deg double amplitude, this figures out to be about 21.2 in-lb per cycle at 330 cycles per min (corresponding to the actual frequency of oscillation with the damper in place as measured by the torsiograph[9]). The measured energy absorption at this frequency,

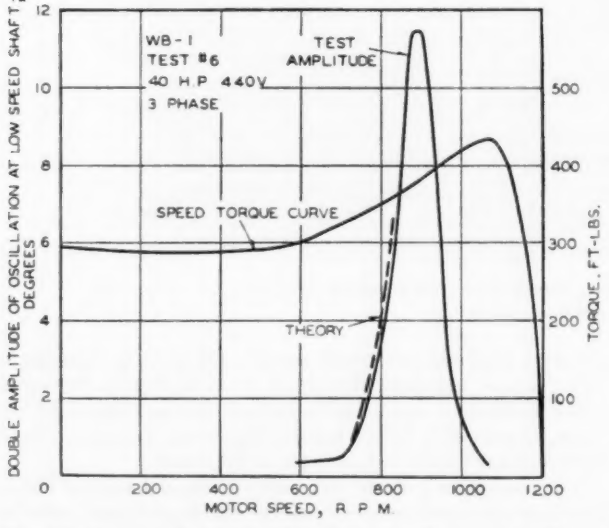

FIG. 17 TYPICAL CURVE OF AMPLITUDE OF OSCILLATION VERSUS SPEED DURING ACCELERATION, FOR SMALL DAMPER

[8] Reference (4), p. 325.

[9] The addition of a damper to the system considered should yield a 2-deg-of-freedom system with two natural frequencies, one slightly below and one slightly above the natural frequency without the damper. The figure of 330 cycles as measured on the WB-2 unit with the damper installed was about 5 per cent below the figure of 348 cycles measured on this unit without the damper. The higher natural frequency was not observed in any of the tests.

Fig. 10, was about 30 in-lb per cycle which indicates that the capacity of the damper was considerably greater than that required to take care of the negative damping at this amplitude; the positive damping present will increase this margin. At a double amplitude of 5.3 deg, the calculated value of energy supplied by negative damping was 9.5 in-lb per cycle which corresponds approximately to the test figure of 10 in-lb per cycle absorbed by the damper, Fig. 11. However, when the energy absorbed by the positive damping present is added to the energy absorbed by the damper, there may be an excess of damping capacity even at this low amplitude. This explains why the oscillation did not build up to this value in some cases.

TESTS TO DETERMINE POSITIVE DAMPING IN SYSTEM

In order to get an idea of the positive damping present in drives of this type, some further tests were made on two of the units. These tests were carried out by putting smaller orifices in the dampers so that the oscillation would build up; torsiograph records during the accelerating period were then taken.

Referring to Fig. 18 for the WB-2 unit with the $^{19}/_{32}$-in. orifice in the damper, a double amplitude of around 6 deg at the high-speed shaft was measured during acceleration. By putting in a $^{7}/_{16}$-in. orifice, the damping capacity of the damper was cut approximately in half at 330 cycles, Fig. 10, the energy absorption per cycle being reduced from about 30 to 16 in-lb. However, as will be seen from Fig. 18, the amplitude built up to only about $7^{1}/_{2}$ deg with this orifice in the damper. By using a $^{6}/_{16}$-in. orifice (energy absorption 9.3 in-lb per cycle) a large build-up occurred. This indicates that at an amplitude of around 8 deg, a $^{7}/_{16}$-in. orifice which gives an energy absorption of 16 in-lb per cycle is sufficient, and hence there appears to be a margin of about 2:1 between the actual damper capacity with the $^{19}/_{32}$-in. orifice and that required to limit the oscillation to about 7 deg at the high-speed shaft (or 1 deg at the low-speed shaft). As mentioned previously, the energy supplied by the motor at this amplitude was 21.2 in-lb per cycle at full voltage. Actually, there was a drop of about 5 per cent in voltage in the tests which would reduce this figure to 19 in-lb per cycle. Since about 16 in-lb per cycle are required in the damper, this indicates that the positive damping in the system (WB-2 unit) is roughly $^{1}/_{6}$ the negative damping in the motor (or about 3 in-lb per cycle).

Similar tests using the large damper on the EK-2 unit are also shown in Fig. 18. Here no appreciable build-up in amplitude occurred with the $^{9}/_{16}$-in. orifice which had about $^{1}/_{3}$ the damping capacity of the $^{13}/_{16}$-in. orifice at the observed frequency of 205 cycles per min, Fig. 9, which again indicates a margin between actual and required damping capacity of about 2:1. A build-up to about 18 deg occurred with the $^{7}/_{16}$-in. orifice in this damper. Referring to Fig. 9, this would indicate that an energy-absorption capacity of something under 11 in-lb per cycle is required to limit the amplitude to say 8 deg. Since the calculated energy supplied by the motor was about 17 in-lb per cycle (corrected for a voltage drop to 420 v as observed), this indicates that the positive damping in the system is about $^{1}/_{3}$ the negative damping supplied by the motor (or about 6 in-lb per cycle).

An estimate of the energy absorption due to hysteresis in the low-speed shaft of the drive was carried out assuming an average figure of 0.02 for specific damping capacity (carbon steel) at an alternating stress corresponding to 8 deg double amplitude at the high-speed shaft.[10] This yielded a figure of about 2 in-lb per cycle. However, in the actual drive, there is a steady stress superimposed on the alternating stress which would tend to raise this figure, while there are also other sources of damping in the

[10] "Damping Capacity of Materials," by G. S. Von Heydekampf. Proceedings, A.S.T.M., vol. 31, 1931, part 2, p. 164.

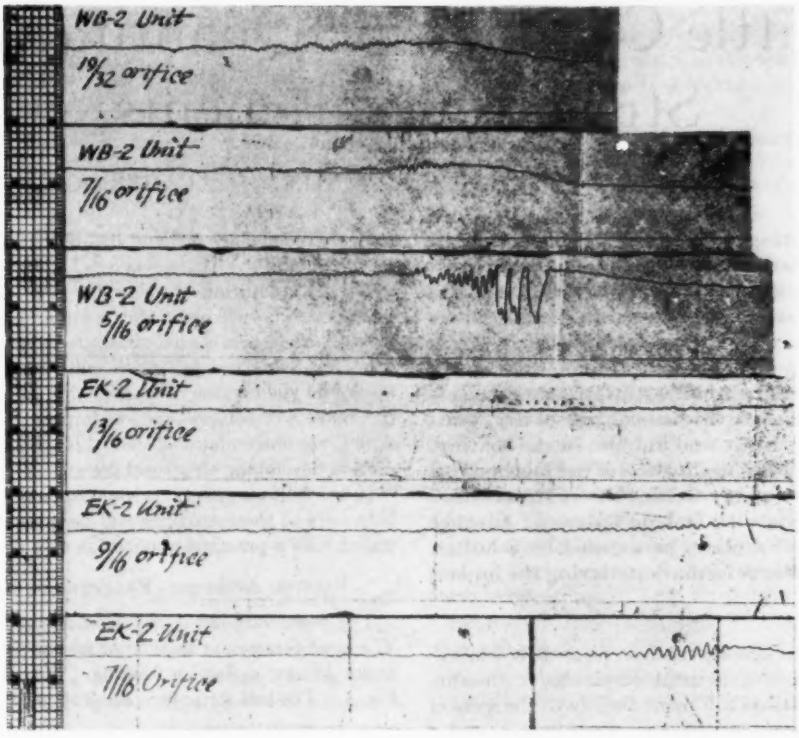

FIG. 18 TORSIOGRAPH RECORDS SHOWING INCREASE IN AMPLITUDE WITH DECREASE IN ORIFICE SIZE
(WB-2 and EK-2 units; scale, 0.085 in. = 1 deg at low-speed shaft.)

bearings, couplings, and gears. Consequently, the figures of 3 and 6 in-lb per cycle, as estimated from these tests, do not appear unreasonable, although they must be considered as very rough.

SUMMARY AND CONCLUSIONS

This study shows that, for a system consisting of an inertia load (such as a heavy fan or blower) which is driven by a low-resistance induction motor, there is danger of torsional oscillation due to negative damping during the accelerating period. If there is sufficient inherent positive damping in the system or drive, or if the accelerating time is relatively short, these torsional oscillations will build up only to a small extent, if at all. This is probably the situation in most induction-motor drives. On the other hand, if, as in the particular drives under consideration, the accelerating time is relatively long, while the positive damping present is low, the oscillations may build up to objectionable magnitudes, so that considerable noise and chatter occur.

Tests carried out on actual drives show that these objectionable oscillations may be eliminated by the use of a relatively simple tuned hydraulic damper mounted on the motor shaft.

For the design of similar drives, formulas are given for calculating the energy-absorption capacity of the damper at various amplitudes and for various orifice sizes. Laboratory tests indicate that a discharge coefficient of 0.8 to 0.9 may be assumed for the particular orifices tested. The use of these formulas in determining the margin between actual and required damping capacity is illustrated by application to an actual drive. Also tests made on two different units indicate that in these cases positive damping of about $^1/_6$ to $^1/_3$ the negative damping supplied by the motor is present. However, because of the considerable variation indicated, it appears advisable in design to neglect the positive damping in calculating the damper capacity unless definite test results are available.

ACKNOWLEDGMENT

The authors wish to express their appreciation to Dr. L. W. Chubb and Messrs. R. E. Peterson and L. A. Kilgore of the Westinghouse Company for their interest in the problem and the suggestions made, to Messrs. S. F. Henderson and F. Richards of the same company for information and advice during the course of the work, and to the Pennsylvania Turnpike Commission for permission to make field tests on the actual drives.

Brittle Coatings for Quantitative Strain Measurements

By A. V. de FOREST,[1] GREER ELLIS,[2] and F. B. STERN, JR.,[3] CAMBRIDGE, MASS.

The use of brittle coatings in stress analysis is discussed in this paper. Particular reference is made to the "Stresscoat" materials and method which can effect quantitative analyses within the elastic range by use of brittle coatings alone. In the plastic range, the flaking off of the coating is shown to be caused by a compression component of strain of about 1 per cent. Graphs and illustrations show the effect of such variables as coat thickness, time of dry, temperature and humidity, creep, and bubbles in the coating. Test procedure is outlined. Application of the method to a part from a high-speed sewing machine shows stress values and correlation of results with fatigue failures. Another application illustrated is a plate, penetrated by a bullet, showing elastic and plastic deformations during the impact loading.

BRITTLE coatings are among the most potentially convenient of strain gages. On the usual complicated engineering structure, such coatings will point directly to the areas of highest strain, show the direction of the principal tension, and if properly controlled can be made to yield quantitative values of sufficient accuracy for practical design purposes. Since fatigue failure in service usually correlates with maximum tension stress on the structure, direct correlation can be obtained between the brittle-coating patterns developed in a laboratory analysis and the likelihood of failure of that same structure in service. The analysis may be run on the structure itself or on models made of machined or cast plastics, cast iron, welded steel, or other material.

Compression strains can also be measured if desired, as long as the structure and its loading remain within the elastic range, by simply allowing the brittle coating to come to a neutral condition while the maximum load is on the structure. Then when the load is released, the relaxing compression strains will react as tension and fracture the coating.

In 1932, Dietrich and Lehr (1)[4] published the first recognized work on the use of brittle coatings for the indication of strains within the elastic range. Their use was purely qualitative in pointing to areas of highest strain and indicating the direction of the principal tension. Quantitative measurements were subsequently made with a special short-gage-length strain gage. Work on a brittle coating which could also be used to determine quantitative values was started in 1937 at the Massachusetts Institute of Technology (2) and has resulted in the present Stresscoat method.

Besides fracturing at relatively low values of tension strain, brittle coatings will also indicate larger values of strain by flaking off the surface of a coated structure in much the same way as the commonly observed flaking of mill scale. The flaking occurs in the initial yield region of most metals and correlates directly with the amount of compression strain present. Haigh (3) has made strong recommendations that this phenomenon be more fully used in developing structural designs.

In the following sections some basic data on the characteristic behaviors of these coatings will be presented and their use illustrated with a practical application to a design problem.

Factors Affecting Fracture of Brittle Coatings

The basic variable is of course the strain patterns produced. The most convenient method of test devised is a cantilever beam under known deflection loading. This apparatus is shown in Fig. 1. The test strips are pieces of spring steel 12 × 1 × 1/4 in.

Fig. 1 Method of Loading Test Strips

The loading rig embodies an adjustment screw at the rear to bring the strip into contact with the cam and a cam of definite deflection. This deflection is such that the upper surface of a coating 0.004 in. thick on the test strip will receive the graduated amount of strain along the strip, as indicated on the scale lying beside the loading rig. The testing procedure is simply to place a coated and dried strip in the loading rig, adjust the strip so that it will just touch bottom of the cam, and deflect the cam to its full extent. Reference marks can be made on the strip opposite the characteristic patterns being investigated, and the strip released from the rig and placed in the scale, from which the amount of strain is read. Tests reported here at other thicknesses of coating than 0.004 in. have been corrected back to this standard value.

Coating Thickness. Variation of the strain patterns with thickness of coating is one of the most important factors. Since it is practically impossible to produce a coating of uniform thickness on all surfaces of an irregular body, it is essential that the strain response of the coating be sensibly constant over a reasonable range of thickness of the coating. Fig. 2 shows a set of strips

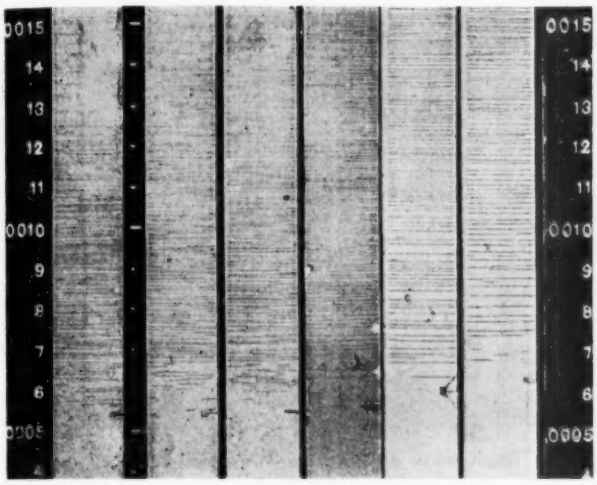

FIG. 2 APPEARANCE OF STRAIN PATTERNS WITH VARIATION IN AMOUNT OF STRAIN AND THICKNESS OF COATING
(Left to right, thickness 0.003, 0.004, 0.005, 0.006, 0.008, 0.01 in.)

with varying thickness of coating. Two characteristics immediately noted are that over the range from 0.003 to 0.006 in. thickness the patterns all start at about the same value of minimum strain, and that the spacing of the patterns becomes wider as the thickness increases. At the higher values of strain, where the spacing is stabilized, the average distance between crack patterns is 5 times the thickness of the coating. The fact that the pattern spacing is so regular and is directly proportional to the thickness of the coating indicates that pattern formation undoubtedly begins on the free surface of the coating. In the regions of lower strain, where the patterns are irregular, the average spacing is approximately 10 times the thickness of the coating. The most reliable quantitative indicators between all the strips are seen to be, first, the value of strain at which pattern formation starts, and next, the degree of regularity in the development of the evenly spaced full pattern.

Time of Dry. Although the coatings set hard enough to handle within a drying time of 5 minutes, the important drying processes which produce sufficient brittleness of coat for elastic-strain-indicating purposes require at least 3 hours before any indications below 0.0020 in. per in. strain can be obtained on a thickness of coating between 0.003 and 0.006 in. Fig. 3 shows how the region of constant strain sensitivity when plotted against thickness broadens as drying proceeds. Experience indicates 15 to 24 hours as the optimum drying time. A factor not indicated on the graph is that coatings dried more than 24 hours become noticeably more erratic in their pattern formation. It is possible to use 6 hours' drying time when necessary, as an experienced operator can maintain uniformity of coating thickness within limits of ±0.001 in. on simply shaped surfaces.

Temperature and Humidity. Atmospheric conditions during the drying and testing period affect the strain sensitivity of the coating. If the changes are gradual, providing that they were not so severe as to "craze" the coating at any time during the drying period, the coating will react as if the conditions which prevail at the time of test had been constant during the previous drying period. The strain sensitivity of a typical coating, when dried at different temperatures but at the same value of absolute humidity, is shown in Fig. 4. Absolute humidity is used as a parameter because it is the condition which usually prevails in a laboratory or in different rooms of the same building which are at different temperatures and are connected into the same ventilating system. Since the best working range for the coatings is in the sensitivity range of 0.0005 to 0.0009 in. per in. initial strain, it is seen that a coating picked for the optimum value of 0.0007 in. will have an allowable temperature fluctuation of ± 5 deg F. Because of the rapid variation of sensitivity with temperature, it is important that all bodies concerned in the same test be maintained at the same temperature.

Sensitivity also varies with change in relative humidity as shown in Fig. 5. However, this is not a critical point in the practical use of the coatings, as it is seldom that the humidity varies by much, except as caused by seasonal changes of weather.

In order to obtain the optimum coating for any condition of temperature or humidity, a graduated series of coatings of varying degrees of brittleness and a selection chart, such as that shown in Fig. 6, are used. The coating numbers apply to the valleys between the curves. The reactions of all coatings under their optimum conditions as indicated by the chart are the same.

Creep. Despite their brittleness the coatings are quite plastic materials. Fig. 7 shows how the amount of strain necessary initially to crack a coating varies with the time taken to reach that load. Correction for creep is an important factor in obtaining accurate quantitative measurements. Correction may be had either by loading all bodies involved in the test in the same length of time, or else by loading at a constant rate, observing the time at which patterns first appear, and correcting all values to a common time of loading by means of a chart similar to that in Fig. 7.

Bubbles in the Coating. The certainty of duplication of a definite strain pattern is enhanced by creating a formation of fine bubbles within the coating through proper spray-gun technique. Comparison of a series of test strips painted with clear coatings on the right and "bubbled" coatings on the left is shown in Fig. 8.

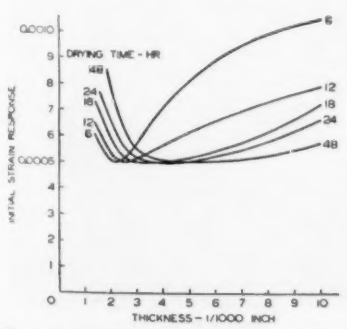

FIG. 3 VARIATION OF STRAIN SENSITIVITY WITH THICKNESS OF COATING AND TIME OF DRY

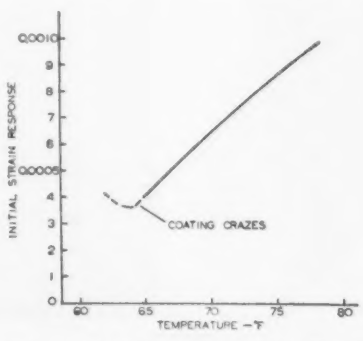

FIG. 4 VARIATION OF STRAIN SENSITIVITY WITH TEMPERATURE
(Absolute humidity maintained constant at 0.37 in. Hg; coating number 1204.)

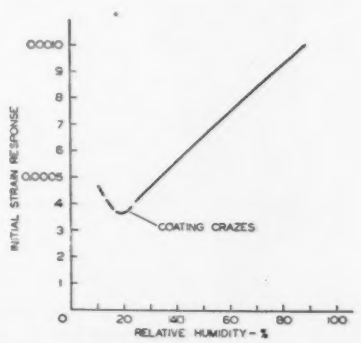

FIG. 5 VARIATION OF STRAIN SENSITIVITY WITH HUMIDITY
(Temperature maintained at 70 F; coating number 1204.)

The clear coatings have the characteristics of being more erratic in the initiation of pattern formation and, further, when a crack is started it tends to extend itself into areas of lower strain. A point of interest here is that there is approximately 6 per cent more tension strain in the center of these test strips than there is at the edges. The bubbled coatings exhibit more certainty of pattern formation in a given area and, further, exhibit less tendency to extend themselves into regions of lower values of strain. There is also some apparent increase in the sensitivity of the coating with bubbles present, but this is not as large a value as might be anticipated. An interesting fact is that the cracks in the brittle coating do not noticeably deviate in their direction because of the presence of bubbles in or beside their path.

All the data, except for the one illustration in Fig. 8, is for coatings with included bubbles.

Factors Affecting Flaking of Brittle Coatings

When the strain on the surface of the coated body has been carried to fairly high values which are at or slightly exceed the yield point of most structural materials, the proper grade of these brittle coatings will flake off. The initiation of flaking correlates directly with the amount of compression strain present, the optimum coating starting to flake at 1 per cent of the maximum compression-strain component,[5] regardless of the type of loading involved. This correlation is illustrated in Table 1.

TABLE 1 AMOUNT OF STRAIN TO INITIATE FLAKING OF COATING UNDER DIFFERENT LOADING CONDITIONS

	Strain	Compression-strain component
Tension loading	$\epsilon_t = 0.02$	$\epsilon_c = \nu_p \epsilon_t = 0.01$
Compression loading	$\epsilon_c = 0.01$	$\epsilon_c = 0.01$
Torsion loading	$\gamma = 0.02$	$\epsilon_c = {}^1/_2\gamma = 0.01$

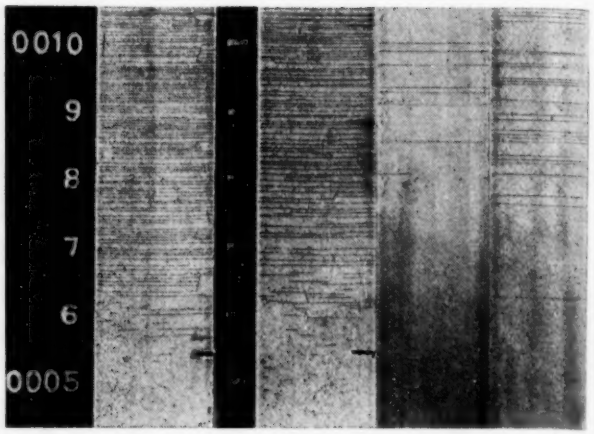

Fig. 8 Comparison of Coatings With and Without Included Bubbles
(Test strips on left have included bubbles.)

[5] It is of interest to note that the best brittle mill scale will flake at $^1/_2$ per cent compression-strain component, but that different mill scales vary widely in their brittle properties.

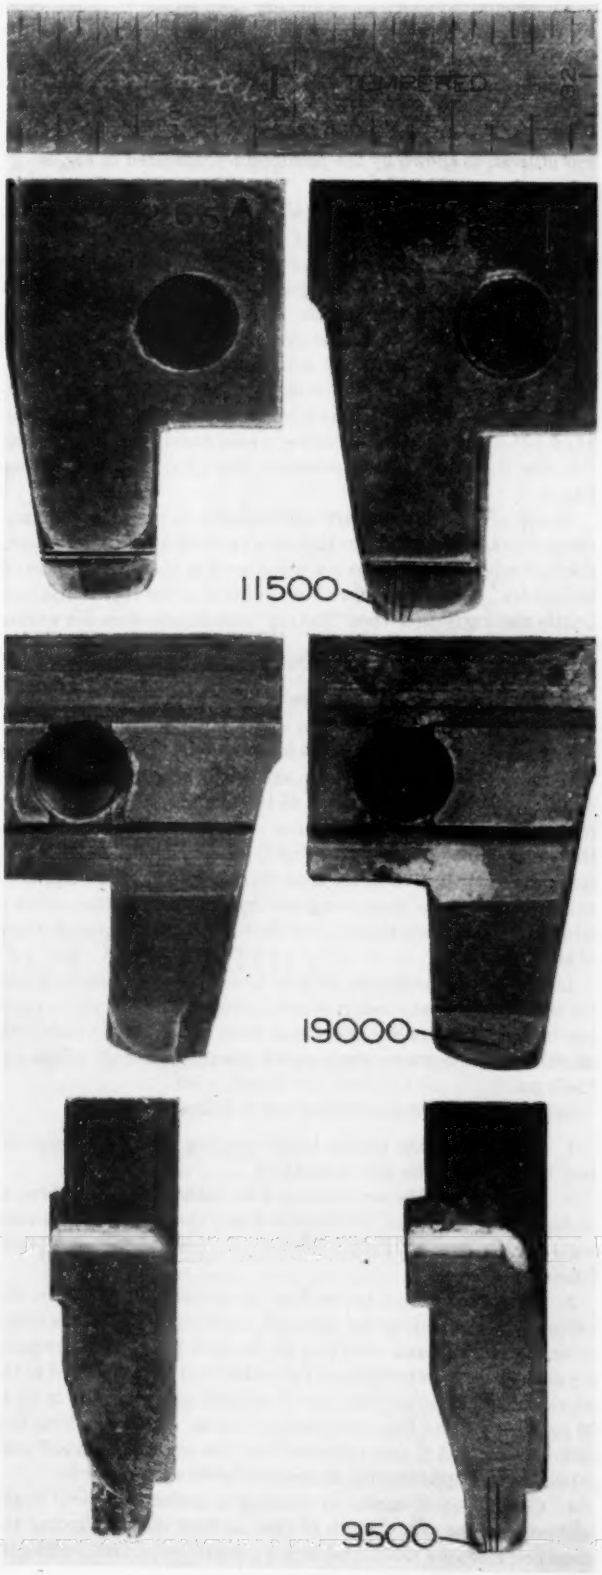

FIG. 13 RESULTS OF STRAIN ANALYSIS ON SEWING-MACHINE HEAD AND COMPARISON WITH SERVICE FAILURE
(Tension stresses in pounds per square inch at 250-lb load. Courtesy of United Shoe Machinery Corporation.)

Those factors, which have already been shown to influence the formation of elastic-strain patterns, differ somewhat in their influence on flaking of the coatings.

Thickness of Coating. Thickness of coating is less critical, as illustrated in Fig. 9.

Drying Time. The necessary drying time is shorter and also less critical, as shown by the point values indicated in Fig. 9.

Temperature and Humidity. The effects of temperature and humidity are moderately critical on the amount of quantitative compression strain indicated by flaking. Figs. 10 and 11 show that there are optimum values of temperature and of humidity at which a given coating requires a minimum amount of strain to start flaking. These optimum atmospheric conditions are the ones which promote a moderate crazing of the coating during drying and correspond to the minimums previously shown in the dotted portions of the curves in Figs. 4 and 5. The optimum coating, which operates at the minimums exhibited in Figs. 10 and 11, is obtained by using a coating whose number is 4 higher than the one indicated on the selection chart for the elastic range, Fig. 6.

Creep. Sufficient data are not available to present an accurate creep chart, but it is known that this variable is less severe than is the case when the coatings are being used as elastic-tension strain indicators. One reason for this condition is the fact that a more brittle coating is used when "flaking" indications alone are wanted.

Method of Making Strain Analyses

The most reliable quantitative indication in the elastic range is the amount of principal tension strain indicated when the strain patterns just start to form. As long as the structure and the distribution of loads remain within the elastic range, all local strains will vary directly in proportion to the amount of load, and therefore the measurement of one value of local strain, at any area at the value of load at which it occurs, will give sufficient data for a complete quantitative strain analysis of the structure. Apparent values of stress are then computed by multiplying the values of strain by the tension modulus of elasticity of that particular part of the structure.

Linear elastic conditions, such as have just been described, hold for the average static setup of solid structures, i.e., engine parts, but in general there are deviations from linear elastic conditions on thin-plate structures such as, for example, aircraft wings and fuselages.

Briefly the procedures for test are as follows:

1 Selection of the proper brittle coating for the temperature and humidity in the test laboratory.

2 Spraying on the structure and the calibration strips, first, an undercoating and then, 15 minutes later, the proper brittle coating, which is usually dried 15 to 24 hours, but may be used within 6 hours if necessary.

3 Running the test by loading the structure to a reasonable value of load, searching for patterns, marking any patterns which have just started, and returning to the base load. After remaining at the base load for at least twice the total time involved in the previous loading cycle, the load is applied again until it is 10 to 30 per cent greater than the previous value. After marking new patterns the load is again released and the cycles continued until patterns have appeared on all areas of interest.

4 Calibration is made by loading a calibration strip in the calibrator in the same length of time as that used in loading the structure, marking the initial strain pattern point and reading its value in the strain scale.

5 After the completion of the test, the patterns may be dye-etched if it is desired to increase their visibility.

Since the patterns will form at high rates of loading, it is possible to get a qualitative analysis of a structure which is loaded under impact conditions. The dye etchant is very useful in such tests, as it will reopen patterns which may have formed during the initial impact condition and then have closed during the subsequent vibration.

Illustrations of the Use of This Method

An interesting correlation between strain patterns obtained on a small machine part in a static test and fatigue failure of these same parts in service is shown in Fig. 13. The part is a sewing head from a shoe-stitching machine. The principal load is the internal pressure created by the plunger forcing the soft leather thread out of the head and through the sole of the shoe. The simple static-loading rig is shown in Fig. 12. Since the value of load which occurs in service is not definitely known, the results were simply computed to an arbitrary amount which gave reasonable values of stress. The exact amount of service stress is not as important as the relative values which will be useful in redesigning the part.

Fig. 14 illustrates a qualitative analysis of strain conditions on the surfaces of a $^3/_8$-in. steel plate penetrated by a 0.30-caliber bullet. In the center is the bullet hole, surrounded by a ring of highly deformed metal Next comes a band in which the coating has flaked off indicating the region of the plate which passed the yield point. The outer area with the coating intact shows the elastic strains present, radial tension predominating on the entrance side, and tangential-tension strain on the exit side.

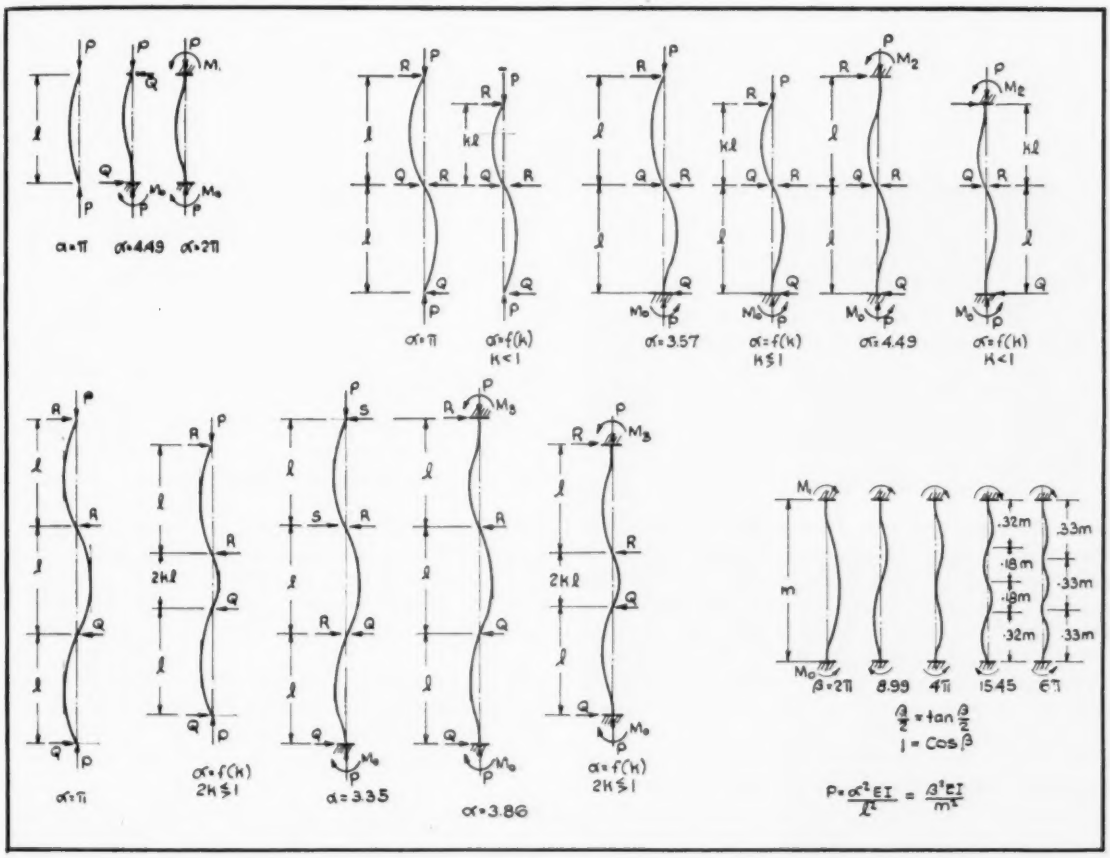

FIG. 1

Long Continuous Columns

BY F. G. SWITZER,[1] NEW YORK, N. Y.

IN connection with a design problem it became necessary to determine the strengths of long columns with intermediate guides. The guides were short, with clearance to the (moving) column and were assumed to offer no restraint to angularity. The solution offered here is the same as the Euler solution so well known for columns of a single loop.

An equation was written for each loop, constants of integration determined from the location of ends and guides on the load axis, and moments eliminated by slope equality through the guides. Buckling loads were finally found by satisfying given end conditions. Higher values of the single-loop solution were also investigated for two fixed ends. These are shown in the lower right-hand corner of Fig. 1.

Some explanation of the solutions, where $\alpha = 4\pi$, 6π, etc., is warranted. The axial tangents at the points of zero deflection are due to *two* guides, at distance zero apart. This interpretation is the same as saying that two points very close together on a

TABLE 1 BUCKLING LOADS AND GUIDE LOCATIONS FOR MAXIMUM LOAD

6	0.24 m, 0.34 m, 0.5 m, 0.66 m, 0.76 m

NOTE: With n odd, the guides are in pairs close together to give, in effect, a fixed end at each pair of guides.

[1] Division Engineer, New York City Board of Water Supply. Mem. A.S.M.E.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until January 11, 1942, for publication at a later date. Discussion received after the closing date will be returned.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors and not those of the Society.

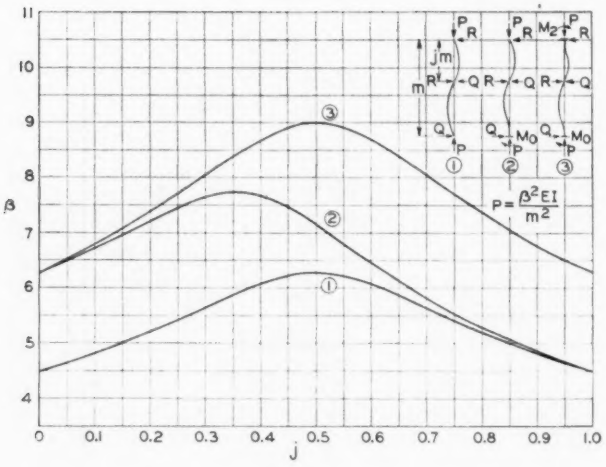

FIG. 2

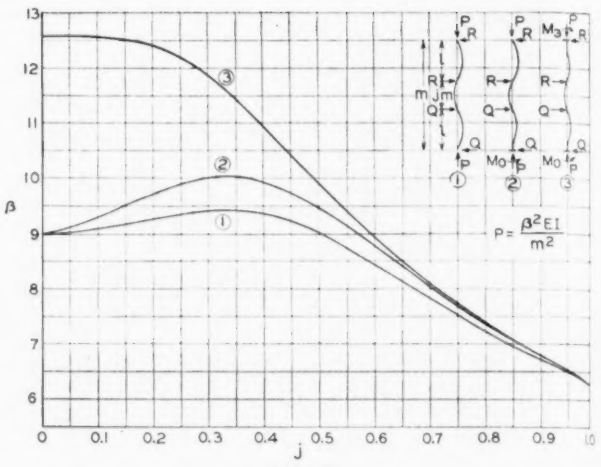

FIG. 3

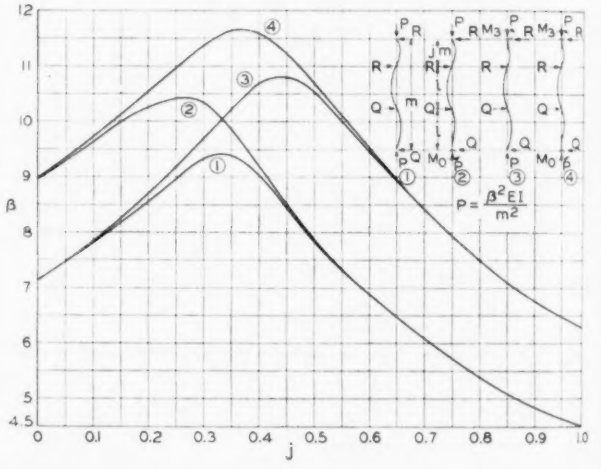

FIG. 4

line determine the slope of the line. Thus with two guides, three loops, and both ends fixed, the guides should be close together at the center and not at the third points as in the case with both ends round. The location of guides for maximum load are determined by the points of zero deflection. It should be noted that these are not equally spaced when the number of loops is even. Table 1 gives buckling loads and guide locations for maximum load, and also buckling loads for columns with equally spaced guides.

Figs. 2, 3, and 4 give buckling loads for long columns of two and three loops with guides at fixed locations. In the sketches of these three curve sheets, an end moment M_0, M_2, etc., indicates a fixed end with axial tangent. The absence of an end moment indicates a round end. The guide reactions Q, R, etc. are transverse forces only. The load is axial and centrally applied.

It has been assumed that these results may be applied to shorter columns than those within the Euler range by the use of a straight-line or parabolic formula derived on the basis of a given crushing stress, factor of safety, and tangency to the appropriate Euler equation, as is customary for single-loop columns.

This study was made in connection with sluice-gate extension-stem designs for the new Delaware Aqueduct. This work is under the direction of the New York City Board of Water Supply, composed of the following members: Commissioners, George J. Gillespie (president), Henry Hesterberg, Rufus E. McGahen; chief engineer, Charles M. Clark; deputy chief engineer, Roger W. Armstrong; and department engineer, Harry R. Bouton.

Discussion

A Short-Gage-Length Extensometer and Its Application to the Study of Crankshaft Stresses[1]

GREER ELLIS.[2] In connection with the use of Stresscoat brittle coatings which the authors mention in step 2 of their three steps in analyzing a structure, the writer would like to add the following information:

As the loading is increased on a structure under test, these coatings will fracture first in areas of maximum tension strain, with the direction of fracture always at right angles to the principal tension.

Compression strains may likewise be indicated as long as the load remains in the elastic range, by reversing the loading and coating processes. Maximum load is maintained while the coating sets to its normal neutral state. Then release of this load allows the relaxing compression strains in the structure to react as tension on the coating.

On practical structures which are usually complicated, qualitative analyses by brittle-coating patterns are great time savers in showing where and in what direction to place the mechanical gage. This is the use of brittle coatings referred to by the authors.

Sometimes, however, areas of interest are so located that the placing of a mechanical gage is difficult or impossible, while the placing of a lacquer film is feasible. Here the quantitative brittle-coating method of analysis, developed recently at the Massachusetts Institute of Technology, with careful handling, can provide values of the principal tension and compression strains to an accuracy of within ± 10 per cent of the true values.

c Plate with hole, in tension, 9000-lb load
d Plate with hole, in tension, 14000-lb load
e Plate with hole, in tension, 17000-lb load

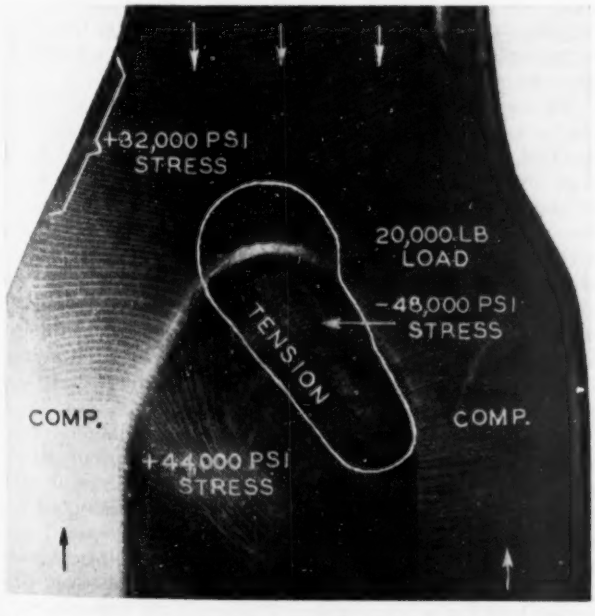

FIG. 1 STRESSCOAT PATTERNS ON FORKED CONNECTING ROD

Fig. 1 shows a forked connecting rod having indications within the crotch as well as on other more open sections. Since the patterns when once formed normally remain visible after release of load, the interiors of assembled structures may be coated, assembled, partially loaded and unloaded, and then disassembled for inspection. Repetition of the process at increasing loads enables one to follow the initiation and growth of all patterns. Even where there is a direct bearing fit, it has been found that the coating applied in a shallow channel $^1/_4$ in. wide and 0.01 in. deep, cut in the area under question, gives satisfactory results.

Fig. 2 illustrates the method of quantitative use. The location and the load at which initial patterns occur are the data taken on the structure. Matching the newly formed patterns on the structure with the lower-range patterns on the calibration strip in the strain scale, at the left, gives the amount of strain present. As long as the loads are kept within the elastic range of the structure, data of one value of strain at one value of load are sufficient for computation of strain at any other value of load by simply proportioning local strains to loads.

Fig. 3 shows the step of loading in the standardized loading

jig, the calibration strip which has previously been coated and dried along with the structure. Under cantilever-beam loading, the upper and lower surfaces of the calibration strip receive a linear gradation of strain from a maximum at the fixed end to zero under the cam. After release from the calibrator, the calibration strip is placed in the strain scale, which is marked off in terms of the strain imposed on the strip by the fixed-cam deflection.

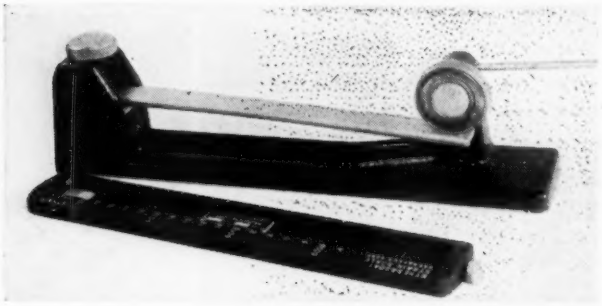

FIG. 3 CALIBRATION STRIP UNDER LOAD IN CALIBRATOR
(Strain scale in foreground.)

AUTHORS' CLOSURE

We agree with Mr. Ellis that brittle lacquer is a useful tool for the study of strains, used either qualitatively in conjunction with the extensometer or quantitatively on other problems, especially those not soluble by other methods.

The use of either brittle lacquer or an extensometer or strain gage permits measurements on the part in question itself. We have found this often to result in a considerable saving in time and expense in studying complicated structures, particularly if two or more parts must be assembled for the test with proper clearances and correct relation (as in a structure consisting of steel and aluminum) between the moduli of elasticity of the parts.

Buckling of the Circular Plate Beyond the Critical Thrust[1]

TH. VON KÁRMÁN.[2] The calculation of the deformation of a plate or shell beyond the buckling limit given by the classical theory of elastic stability requires the solution of a system of nonlinear partial differential equations. Because of the mathematical difficulties, until now only approximate solutions have been produced. The validity of these approximations is restricted either to the neighborhood of the buckling limit or to the very large value of the ratio between the actual and the buckling load. It is very fortunate that the authors found a special case in which the integration of the partial differential equation can be actually carried out so that the approximate methods can be checked. For this reason, the writer believes that this paper represents a definite step forward in the development of the theory of finite deformation.

It would seem that the simple method, which the writer applied years ago to the calculation of the ultimate stress of a flat square plate, supported freely along the longitudinal edges, might also be applied in this case, leading to a relation for the edge stress and buckling stress similar to that obtained by the authors, based on their asymptotic method of integration. The numerical constants involved in this relation might be different, since the writer's method represents a somewhat crude approximation. However, the form of the equation obtained by the two different methods is identical.

AUTHORS' CLOSURE

We have followed the suggestion of von Kármán and applied the Rayleigh-Ritz method to our problem; formulas of the correct type can thus be derived. In the treatment of von Kármán a simple assumption relating to the distribution of the membrane stresses was made. Instead, it is just as simple to determine the membrane stresses together with the bending stresses from the Rayleigh-Ritz method; then even a close numerical approximation can be obtained.

In the terminology of section 6, the potential energy is proportional to

$$V(Q) = \int_0^\infty \left\{ \left(\frac{dP}{d\beta}\right)^2 + \left(\frac{dQ}{d\beta}\right)^2 - PQ^2 \right\} d\beta$$

where

$$\frac{dP}{d\beta} = -\frac{1}{2}\int_\beta^\infty Q^2 d\beta \quad \text{.....cf [31]}$$

The function $Q(\beta)$ was assumed to be of the form $Q(\beta) = ag(\beta/b)$ and $V(Q)$ was minimized with respect to the parameters a and b. The membrane stresses were then obtained from $P = 1 + \int_0^\beta \frac{dP}{d\beta} d\beta$. Various assumptions were made for the function g; the closest approximation resulted from $g = (1 - \beta/b)^2$ for $0 \leq \beta \leq b$, $g = 0$ for $\beta \geq b$. We find, for example, 0.76 for the right member of Equation [37] instead of 0.728, while the tensile stress p_0 at the center is given almost exactly by $p_0 = -0.47\, p_r$.

That these results are so accurate is of course because of the fact that the correct asymptotic expression for the potential energy has been taken, i.e., that which leads to the asymptotic differential Equations [31, 32]. It would be highly desirable to refine the method which was introduced by von Kármán for the square plate along the same lines. Unfortunately, the proper asymptotic expression for the potential energy is not known for this case.

The authors have also made use of the Ritz method in attempting to decide the question raised in the paper as to whether the buckled state with radial symmetry might become unstable at high pressures, and a "second buckling" in waves relative to the original buckled state ensue. Lengthy computations have led always to negative results, i.e., the symmetrically buckled state seems, surprisingly enough, to be always stable. While the high concentration of compressive circumferential membrane stress in the boundary layer favors buckling into waves, this tendency would seem to be overbalanced by the small width of the boundary layer and by the positive contribution of the membrane stresses to the potential energy (the latter contribution is lacking in linear buckling problems).

Quite a different question is whether stable equilibrium states with nodes exist for which, under the same edge pressure p_r, the potential energy is lower than that of the radially symmetric state, even if the latter state is stable. Calculations by the Ritz method seem to indicate that this is also not the case and, hence, a sudden jump from one equilibrium state to another of lower energy seems not likely to occur. It is likely, however, that second buckling or jumping over will occur if the edge constraint is slightly weakened.

The Mechanism of Cavitation Erosion[1]

J. C. HUNSAKER.[2] The high-pressure tests on fused-quartz and glass specimens are interesting because they suggest that the liquids may have penetrated the surface of the glass or quartz. Three new experiments suggest themselves:

1 The repetition of the high-pressure tests on metal specimens.

2 The definite establishment of the presence of liquid molecules beneath the surface of a glass or other specimen previously immersed in the liquid under high pressure.

3 The testing of the protection against cavitation, afforded by previous immersion of a metal or other specimen in oil at high pressure.

The author states that cavitation and damage were produced at the surface of a vibrating specimen when the direction of motion of the surface was parallel with itself. A more complete description of the experiment is desirable to show how this motion can produce cavitation.

There is experimental and theoretical evidence available which shows that the maximum pressures occurring under damage-producing conditions in cavitation (1, 2, 3),[3] water impact (1, 2, 3), or compression-wave impingement (3, 4) are on the order of 5000 to 10,000 psi. This value is about 1 per cent of that which the author speculates may be reached.

Ackeret and de Haller (4) describe experiments on a compression-wave apparatus, in which they claim that no cavitation occurred, but during which damage was produced on metal and glass by very steep-fronted compression waves in water and gasoline. The amplitude of these waves was of the order of 3000 psi. On the other hand, no damage was caused by sinusoidal waves, even with amplitudes greater than 7500 psi. The frequency of each type of wave was about 16 cycles per sec. The pressure amplitude, measured by a piezoelectric crystal, was in fair agreement with that computed theoretically. The same authors also report measurements on instantaneous pressures in a cavitating venturi tube and in a water-impact machine (1).

At the Massachusetts Institute of Technology (5), photographs of the cavitation in a magnetostriction apparatus have been taken, from which have been made computations of the pressure-time relation at the test surface. The results show that the pressure is suddenly applied, once during each cycle, and that the maximum pressure is on the order of 6000 psi. The frequencies used were 5300 and 8750 cycles per sec.

These experiments indicate that a sudden application of pressure, on the order of 10,000 psi, causes damage, while a less rapid application of the same pressure may not do so. Further investigation of the effect on damage of changes in suddenness of application is necessary.

J. M. MOUSSON.[4] The author suggests that pitting due to cavitation is the result of fluid injection in molecular form under extremely high pressure. Actual failure supposedly takes place after the sudden release of the pressure due to the insufficiency of the cohesive forces of the material to retain the injected fluid particles. This is not the first time that such a theory has been proposed (6). However, despite the data made available in this paper, fluid injection under cavitation conditions does not appear to be substantiated. Moreover, a preponderance of evidence previously available would seem to be against it.

The results presented in the author's Fig. 1 indicate that fluid penetration requires extremely high pressures as well as a sustained pressure application; that is, the pressure must necessarily act over a sufficient length of time. Under cavitation conditions neither requirement may be fulfilled. While at first glance infinitely high stresses may be thought possible under impact due to collapsing cavities and vortices (7, 8), there are definite limitations in the magnitude as pointed out by Ackeret and de Haller (3). Even under extremely high relative velocities between fluid and boundary, that is, from 100 to 300 fps, the maximum stress may more likely be of the order of tens of thousands rather than hundreds of thousands of pounds per square inch (Fig. 1), or even 1,000,000 psi, as suggested to occur under cavity collapse. Stresses of the latter magnitudes are not only highly improbable but are believed to be unnecessary as a cause for severe pitting due to cavitation. The photomicrographic analyses of many low- and high-alloyed steels and nonferrous-metal specimens in various conditions have indicated that pitting as a result of cavitation is due to repeated pounding or pressure waves causing breakdown phenomena typical of this type of stress application (9, 10, 11). The phenomena observed were: Cold working, as evidenced through surface strain hardening, slip bands, and in certain instances twinning of crystals; yield in surface layers; fatigue cracks caused either by exhaustion of the capacity to yield or by reaching fatigue limits; cracks resulting from stress concentrations due to unfavorable grain shapes; break-throughs between impurities or nonmetallic inclusions or because stratification provided little bond between successive grain layers, etc. Keeping in mind that all these phenomena are the result of a very large number of stress applications, the stress magnitude may more likely be of the order of tens of thousands, rather than of hundreds of thousands, or even 1,000,000 psi.

In addition, two other factors should be given careful consideration. On the one hand, inter- or transcrystalline injection of fluid apparently requires a time interval during which these very high pressures are applied (refer to Fig. 1 of paper). Under cavitation conditions, the entire cycle from pressure rise to dissipation of energy is almost instantaneous. On the other hand, various practical experiences could be cited; although one of these may be sufficient. In some cases, cast carbon-steel propeller turbine blades have seriously pitted during relatively short periods of service, yet repairs of a permanent nature were possible by means of welded stainless-chromium-steel surfaces. Now, if the stresses under fairly severe cavitation conditions were of a magnitude as suggested in this paper, and if pitting were caused because of fluid injection, even the welded stainless steel could not possibly withstand the attack.

There has been an indication that cavitation as produced by means of magnetostriction oscillators may not necessarily be identical to that occuring in flowing water and simulated by test stands of the Venturi or nozzle type. The results obtained with the two types of apparatus check each other only along general lines but not in detail. This contention is illustrated very clearly by means of a comparison between the data obtained at the Massachusetts Institute of Technology (12), and at Holtwood (10), with oscillator- and Venturi-type apparatus, respectively. The author throws additional light on the subject in stating that stroboscopic observations at his laboratory showed vapor bubbles to form at the same point time and again. This phenomenon is not identical to that in flowing water where successive blows may fall at random anywhere in the target area producing a kneading type of stress application. Thus identical

results can hardly be expected with both types of laboratory methods.

The author states that there was no consistency between the pitting resistance of alloys and hardness. Without further qualification, this statement may be misleading. As hardness is not the only criterion to be considered, a consistent relation between hardness and pitting resistance may not be expected unless all other factors to be reckoned with remain unchanged, such as chemical composition, susceptibility to strain hardening, capacity to yield, fatigue limits, grain shapes, percentage of impurities, and nonmetallic inclusions, etc. With a change in material too many other factors change besides the hardness. For instance, taking those referred to by the author, lead and rubber can absorb substantial energy by means of plastic deformation, whereas, glass, cast iron, and carboalloys are very brittle. Rubber is particularly unusual because of its resilience. A series of tests with various types of protective rubber covers cemented to steel plates was made some years ago with the Holtwood cavitation test stand. The results indicated that the thinner the rubber sheet, the higher is the pitting resistance. Apparently appreciable heat is generated within the rubber sheet under the punishment by cavitation, and if this heat cannot be carried away quickly it may melt the rubber. While with thick rubber coverings heat is stored up, thin rubber sheets may apparently give off heat at a fairly rapid rate to the adjacent metal. This phenomenon may perhaps explain the results obtained by the author with molecular oil films.

F. G. Switzer.[5] The first part of this paper is interesting and informative. The data on the failure of glass and quartz upon the removal of pressure are not questioned. However, the writer is unable to follow through to the conclusion that this is the mechanism of cavitation erosion. It appears to be a well-established fact that cavitation erosion occurs in conjunction with the appearance and subsequent collapse of vapor bubbles in a flowing liquid. The collapse of the vapor bubbles results in the generation of high-pressure impacts lasting, as the author states, only a very small fraction of a second but repeated over and over again. The first part of the paper shows conclusively that the high pressure must be maintained for a substantial time of some seconds before failure is caused by the relief of the pressure. Under cavitation conditions, the high pressure does not last long enough to permit the entrance of liquid into the pores of the solid. Is it not much more likely that cracks in metal parts subjected to cavitation are fatigue cracks?

Author's Closure

In response to the various questions raised, concerning the material presented and the conclusions drawn, upon which was based what appears to the author to be the most logical explanation of the mechanism whereby tiny fragments are removed from the surface of a solid in the process commonly referred to as cavitation erosion, the author would like to make the following statements.

Although some experiments have been conducted along the line of those suggested by Professor Hunsaker before it became necessary temporarily to discontinue the work in favor of more urgent matters, additional work along these lines is definitely indicated. In connection with investigations involving high-pressure windows, it was observed that the window would be less likely to fracture in contact with water under pressure if previously it had been subjected to very high oil pressure, thus indicating but not proving an actual penetration.

In those specimens where the direction of motion was parallel with the surface of the specimen, the nickel tube was placed in a horizontal position, and a drop of water was placed on the top surface on the edge of the specimen. In this manner it is impossible for a compression wave to be set up by the movement of the flat surface of the specimen and travel through the liquid, around the corner of the specimen to produce the erosion on the specimen edge. However, the relative motion of the specimen with respect to the water produces the necessary rate of shear and turbulence in the water to produce cavitation and the resultant erosion. The experimental results of citations (1, 2, 3, 4) seem to be quite in agreement with the results obtained by the author, in that he has been unable to obtain any damage by means of a sinusoidal wave in the absence of cavitation.

It is the author's belief that, in spite of the fact that cavitation was not detected by Ackeret and de Haller (4), such was actually taking place whenever damage was produced, and that it would be impossible to measure directly the extremely high and localized pressure resulting from the collapse of the individual cavities. Perhaps one of the best indications that cavitation is actually taking place, and that it is the extremely high pressure localized at points on or near the surface, is that a compression wave, with sufficient amplitude to produce cavitation and therefore damage, ceases to produce damage when a hydrostatic pressure sufficient to prevent cavitation is superimposed on the liquid. If the superimposed hydrostatic pressure is equal to the pressure resulting from the sinusoidal compression wave, it is difficult to understand how doubling the maximum pressure could cause the erosion to cease. The author, therefore, contends that such a superimposed pressure merely prevents cavitation and the resultant extremely high and highly localized pressure sufficient to produce damage. It is also his contention that the mechanism described seems to be in agreement with the experimental data and theoretical consideration.

The fact that it is necessary to maintain pressure on a piece of glass for some seconds to obtain complete rupture of the piece of glass in a single cycle in no way indicates that, if such a pressure were applied several thousand times a second, it would not produce sufficient penetration during each cycle to give a rather rapid erosion. While the author makes no claims that pressures as high as 100,000 psi are necessary to produce erosion, it seems apparent that, since superimposing a hydrostatic pressure would tend to prevent and does minimize and in many cases prevent erosion, a pulsating pressure of only a few thousand pounds per square inch in most cases is insufficient to produce erosion of the type under discussion.

Since there seems to be no direct method of measuring the magnitude of the pressure caused by the collapse of a small cavity because of the extremely small space involved, and the fact that from theoretical considerations one would expect extremely high pressures to be produced, some indirect methods such as the one described can be a very helpful guide. As pointed out in the first of the paper, so many phenomena are involved in such a process that it is difficult, if not impossible, to isolate them completely. The mechanism described has served as a very useful tool in effecting a material reduction and in some cases complete elimination of erosion in certain commercial applications.

Self-Excited Oscillations in Dynamical Systems Possessing Retarded Actions[1]

H. Poritsky.[2] The general conclusions reached by the author that self-excited oscillations might be due to retarded action, even if the latter occurs in a damping term, is of great interest. The term "hysterodifferential equations," used by the author for signifying the fact that there is a phenomenon of lag or hysteresis involved in the action, is more properly applied to cases where the "memory phenomena" extend not only to one preceding time instant but to all the past history of the system, for instance, in case of certain highly viscous solids. The title "retarded action" is more appropriate to the case at hand.

Mathematicians call differential equations which involve values of the function or its derivatives at t and $(t - \Delta t)$ "difference-differential" equations. The fact that a difference-differential equation is equivalent to a linear differential equation of infinite order, while of great interest, is hardly of any help in the actual solution of the problem. This solution may be obtained by assuming outright an exponential solution. Thus, assuming a solution of the author's Equation [4]

$$\theta = e^{\lambda t} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots [1]$$

where λ is a proper constant, and substituting, there results upon factoring out the exponential $e^{\lambda t}$ the following equation for λ

$$J\lambda^2 + B\lambda + C + S\lambda e^{-\lambda \cdot \Delta t} = 0 \quad \ldots\ldots\ldots\ldots [2]$$

In general a linear difference-differential equation admits exponential solutions in a manner quite similar to that of an ordinary linear differential equation, except that, whereas in the latter case the determination of the exponents reduces to an algebraic equation, in the present instance it reduces to a transcendental one. There may now be an infinite number of exponentials. Instability obtains when a root exists with a positive real part.

The writer's colleague, Mr. C. Concordia, has called attention to a treatment of a similar problem of retarded action for synchronous-machine generators with regulators admitting a constant time of retardation, by Fritz Reinhardt.[3] The difference-differential equation treated in this case agrees precisely, except for notation, with the one discussed by the present author. The stability and other factors are discussed at great length.

Without wishing to detract from the value of the author's interesting investigation, the writer would like to point out that it is unlikely that even the system illustrated in the author's Fig. 1 possesses an exactly constant time of retardation. Very often in follow-up systems, the retardations are due to neglected inertias of moving parts. When these neglected inertias are taken into account, the order of the system is raised and instability sometimes appears. Again hunting may be due to lost motions such as might occur because of loose fitting between a pin and a sleeve bearing. That the latter may give rise to self-excited oscillations has been shown by C. Concordia[4] and others by means of differential-analyzer studies, and by the writer (in an unpublished paper) by direct investigation of linear systems.

Author's Closure

Mr. Poritsky raised a number of questions which can be discussed here only briefly.

As regards the classification of differential equations, the term "difference-differential equation" mentioned by Mr. Poritsky is probably more generally used than the term "hysterodifferential equation" used in this paper.

Equations in which the "memory phenomena" extend not only to one preceding time instant but to all the past history of the system are generally designated as "integrodifferential equations" following the nomenclature of V. Volterra.[5]

Equation [7′] of the paper by Fritz Rheinhardt,[3] cited by Mr. Poritsky, coincides exactly with the author's Equation [4], derived independently. Additional difference-differential equations encountered in the theory of controls are indicated in the paper.[6] More specifically, Equation [1] of the paper is the equation of a retarded automatic steering control with a purely directional control, and Equation [4] is encountered in the problem of water-ballast control in antirolling ship installations.

Consideration of the difference-differential equations as a limit of an ordinary differential equation of infinitely high order is helpful for two reasons:

1 From the latter point of view, the solution $e^{\lambda t}$ becomes obvious, although, from the former point of view, it is not so obvious.

2 Furthermore, if time lags are small, and the Taylor's expansion 3 converges rapidly, it is frequently convenient for numerical computations to neglect the terms of higher orders and consider only the first few terms of the expansion. In this manner, one has still an ordinary differential equation but of a higher order instead of a difference-differential Equation [8]. Such methods of approximation are described in a recent paper.[7] The increase in the order of the equation mentioned in the last paragraph of Mr. Poritsky's discussion appears then as the result of these approximations. If, however, one deals directly with the difference-differential Equation [8], there can be no question of raising its order, since this equation is nothing but an asymptotic

form of an ordinary differential equation of an infinitely high order.

As regards the hypothesis concerning the constant time lag, like any other hypothesis, it is valid only if the experimental evidence justifies such an assumption. In experiments described in connection with Fig. 1, of the paper, the power of the motor was sufficiently great in comparison with the power needed to accelerate the weight and overcome its friction. The pendulum was rocked by a cam within a certain range of frequencies ω and moving pictures of the angle θ and the displacement x were taken. From the record of angle θ, a curve $\dot{\theta}$ of angular velocity was plotted and the phase angle $\varphi = \omega \Delta t$ between the $\dot{\theta}$ and x curves was thus obtained; from these computations it was found that the time lag Δt proper (as distinguished from the angular lag φ) was fairly constant, as was assumed in the theory.

Finally, in order to establish the existence of instability, it is sufficient to show that there is at least one positive root, as Mr. Poritsky points out and as is mentioned[8] in the paper.

[8] Ref. 1, p. A-67.

The criteria for stability are, however, more restrictive, since they require that the real parts of all roots must be negative. This condition is generally obtained by means of the so-called Hurwitzian criteria. The application of these criteria to Equation [14] of the paper presents no difficulty. It is not included here, because the purpose of the paper is to establish the conditions for instability rather than those for stability.

Finally, as regards the question of the stability of the amplitudes of self-excited oscillations (as distinguished from the question treated in this paper concerning the zones where these oscillations may occur), it can be stated that such stable self-excited oscillations can never occur in purely linear systems and are always associated with what Poincaré calls the "limit cycles" (cycles limites) of nonlinear systems. The relaxation oscillations studied by Van der Pol are typical in this connection, and it is to be expected that both mechanical and electromechanical systems must possess these features of nonlinearity if self-excited parasitic oscillations are to exist in a steady state. As far as is known, this question remains still relatively unexplored.

Book Reviews

Water and Carbon Dioxide

PROPERTIES OF ORDINARY WATER-SUBSTANCE. Compiled by N. Ernest Dorsey, Physicist, National Bureau of Standards, Washington, D. C. American Chemical Society Monograph Series. Reinhold Publishing Corporation, New York, N. Y., 1940. Cloth, 6 × 9 in., xxiv and 673 pp., $15.

CARBON DIOXIDE. By Elton L. Quinn and Charles L. Jones. American Chemical Society Monograph Series. Reinhold Publishing Corporation, 1936. Cloth, 6 × 9 in., 294 pp., $7.50.

REVIEWED BY JOSEPH H. KEENAN[1]

THE book by Dorsey is an amazingly comprehensive and complete collection of data on the properties of water in all its known phases. The plan of the compilation was made by a committee of the Bureau of Standards, but the reality is evidently the product of the diligence and skill of the author.

The backlog of the project is the International Critical Tables which provided information antedating January 1, 1923, though even this material has been supplemented. Information of later date was obtained by carefully combing the technical literature of all the civilized world.

Like the International Critical Tables this book presents source material rather than working tables such as the engineer employs. For example, one finds here all the data that have been used in the preparation of *steam tables* for engineering purposes, but not the *steam tables* themselves.

The material is of greater variety than would be required for ordinary engineering uses. Data are given on dissociation, heat of formation, characteristics of the molecule, rates of diffusion in various media, optical properties, emissivity, absorptivity, fluorescence, electrical characteristics, strength of the liquid in tension, photoelectric effects, and color.

The curiosity seeker will find here things to tickle his fancy. Samples of water taken from different depths of Lake Baikal had different densities, even after distillation. Negative pressures of 2300 lb per sq in. have been sustained by ordinary water. A reputable theory of the structure of ice maintains that "ice is a liquid jelly, with foam-walls of concentrated oily salt solution, which enclose foam cells containing viscous, doubly refracting, pure or nearly pure water."

The book is often difficult to read because the same type is used for text and tables. Where the text is interrupted by tables, which often extend over several pages and include explanatory paragraphs, the reader is sometimes at a loss to find the end of the interruption.

The vocabulary is occasionally troublesome, at least to the engineer. For instance on page 78 we learn that "by dilated water vapor is meant the vapor at a pressure that is less than its saturation pressure at the temperature concerned. The adjective 'dilated' is less ambiguous than the more frequently used 'unsaturated,' which is equally appropriate to the supersaturated condition." It appears that the author is unaware of the term *superheated vapor*, which has a more honorable history and far more general acceptance than the term *unsaturated* which he quotes. On page 271 we find that "the heat liberated by adiabatic compression" is the constant-temperature coefficient, $(\partial h/\partial p)_t$. This is a curious use of the term *adiabatic*. On page 269 it is stated that "the Joule-Thomson coefficient . . . . . is the increase in temperature on adiabatic compression."

These minor deficiencies should not, however, be overemphasized. The book is of first importance. To anyone working with H_2O it is the International Critical Tables brought up to date. It is something more than that, however. The Critical Tables are a mere skeleton of data. This book has flesh on its bones.

Dorsey devotes 670 pages to water; Quinn and Jones require less than half this number for carbon dioxide. And this despite the fact that half the discussion of carbon dioxide relates to manufacture and use—topics which do not appear in the volume on water.

The data on the properties of carbon dioxide are always meager and often questionable. It is a pity that the resources and the organization that until recently existed in America for research on water were not employed for research on carbon dioxide.

Nevertheless, many interesting items of information can be found among the data in this book. At high pressures solid CO_2 can exist at temperatures appreciably higher than the critical temperature. If water behaved similarly, ice could be red-hot. Fig. 14 in the book shows the Joule-Thomson coefficient as a function of pressure and temperature for liquid and vapor phases and above the critical point.

Although certain limited natural supplies of carbon dioxide rival soap in purity, the gas is commonly manufactured at low cost from products of combustion of fuel and from other sources. Descriptions are given of the manufacturing processes.

The manufacture of dry ice is considered in detail and the various processes employed are shown in diagrams. The preparation of the product for the market and its industrial uses are described.

The book is a happy combination of the scientific and the industrial points of view. The first half is a scholarly presentation of scientific data; the second half is an excellent presentation of engineering and manufacturing methods. If collaboration of a chemist and an engineer can be so fruitful it should be more common.

Materials Testing

MATERIALS TESTING. By Herbert J. Gilkey, Glenn Murphy, and Elmer O. Bergman, McGraw-Hill Book Company, Inc., New York, N. Y., 1941. Cloth, 8½ × 11 in., xii and 185 pp., $2.75.

REVIEWED BY W. M. MURRAY[2]

THIS book represents about twenty years' development of a manual for instruction in the fundamental principles of testing materials and their relation to various phases of engineering. Although the book is intended primarily for an introductory course, it has been prepared in such a manner as to indicate many of the more advanced aspects of testing. The authors have succeeded in the happy combination of a simple elementary text which is well written and easy to understand together with many suggestions showing how the procedures can be utilized in actual engineering practice.

The text is divided into twelve chapters starting with a detailed discussion of strain gages and testing machines. From the

[2] Assistant Professor of Mechanical Engineering, Massachusetts Institute of Technology, Cambridge, Mass. Mem. A.S.M.E.

point of view of a man already familiar with the subject this initial chapter might well be omitted, but for the beginner it will be of great interest and utility both because of the detailed illustrations and the variety of the equipment discussed. The second chapter is devoted to properties of materials and the third to the interpretation of test observations into terms of material properties. A section is devoted to the detail of each of the following types of tests: Tension, compression, shearing, and torsion, flexure, column, hardness, fatigue and impact, a long chapter on tests for concrete, and finally the text is concluded with a chapter on experimental aids in stress analysis.

Throughout the book there are numerous diagrams and detailed work sheets laid out to aid the student, as well as many questions and answers which have been designed to stimulate further study. As an aid to instructors a number of definite problems have been included to form the basis of a course which might be supplemental to lectures in applied mechanics or given as an independent subject.

One noticeable feature of the book lies in the fact that any student using it will be forced to consult the A.S.T.M. Standards very frequently. This will undoubtedly give excellent training in looking up references.

The writer regrets that the detail of the first few chapters is not maintained throughout the text. This is particularly noticeable in the chapters on hardness, impact, and fatigue which are not nearly so complete.

Although the book is elementary in character it includes an excellent list of references which carry on well beyond its own scope and for that reason it should prove most valuable to the beginner since it will indicate the direction in which to proceed after its own contents have been absorbed.

Thermodynamics

THE NATURE OF THERMODYNAMICS. By P. W. Bridgman. Harvard University Press, Cambridge, Mass., 1941. Cloth, 5¼ × 8 in., xii plus 229 pp., $3.50.

REVIEWED BY J. H. KEENAN[3]

PROFESSOR Bridgman states his object as follows: "to make an operational (as distinguished from a purely logical) analysis of the situation in thermodynamics and related fields, and at the same time cast the analysis in such a form as to bring out the role and consequences of the verbal requirements which have entered into forming the concepts. I shall attempt especially to make clear whether the operations involved are instrumental operations or 'paper and pencil' operations." The result is a distinct contribution to our literature of thermodynamics. It will help the advanced student, but many of the difficulties discussed are of too sophisticated a nature for the beginner who faces enough hurdles within his own scientific experience without having more dragged in from unfamiliar fields.

The discussion of temperature is good, but the treatment of heat and work is not clarifying. We find that the equation

$$dE = dW + dQ$$

"is also applicable . . . . . to regions in which the content of material substance is continually changing, as when it is applied in hydrodynamics." One's first impulse is to say that the example of a steam turbine adequately disproves this statement. But concealed in dW and dQ are Poynting vectors which make everything all right.

This vector concept leads to much argument which appears to end in anticlimax with the statements "it is not possible in general to analyze a flow of energy into two factors, one of which has all the properties of the velocity of a material thing," and "the probability is that even if such an analysis (of entropy flow into a velocity factor and a density factor) is possible, the necessity for it can be sidestepped."

Despite these criticisms, one finds many admirable features in the book. A good discussion of friction at the boundary surface of a system emphasizes the need for discretion in selecting the position of the boundary. The first law is stated in the form "dE is a perfect differential." The section on "the meaning of ΔE" is excellent. Concerning reversibility we read that "it is the recoverability of the original situation that is important, not the detailed reversal of the steps which led to the original departure from the initial situation." In the discussion of the definition of entropy we find this illuminating comment, "the entropy is in the first instance defined by means of reversible processes, just as energy was in the first instance defined for processes for which dW and dQ had a meaning."

The entropy of the universe is discussed intelligently and not in catch phrases, and there are helpful comments on the entropy of radiation. There is frequent reference to a new technique for analyzing irreversible processes which was discussed in the author's book on electrical phenomena in metals but which, unfortunately, is not restated here.

Kelvin once restricted his statement of the second law to inanimate agencies. On this point Bridgman has some interesting things to say, and his conclusion is that "as far as I am concerned there is not the slightest indication that such a conclusion (namely, that vital phenomena are outside the range of thermodynamics) will ever be necessary."

PRESIDENT

Craine

JAMES W. PARKER
1941-1942

James Wentworth Parker

James Wentworth Parker, President of The American Society of Mechanical Engineers for the year 1941-1942, is vice-president and chief engineer of The Detroit Edison Company, and has his residence in Ann Arbor, Michigan. He was born in Auburn, New York, in 1886, of people who had lived in that state for a generation or more but had originally come from New England. His family moved to Kentucky when he was four years old and his boyhood was spent in Louisville.

He prepared for college in the Louisville Male High School and was graduated from Cornell University in 1908, with the degree of mechanical engineer. In 1935 he was awarded the honorary degree of master of science in mechanical engineering by the Detroit Institute of Technology. He is a member of the honorary societies of Sigma Xi and Tau Beta Pi.

After graduation from Cornell, Mr. Parker served an apprenticeship, first with the DeKalb Power & Light Company in Illinois, and then with the Vincennes Street Railway Company, Vincennes, Ind. In 1910 he moved to Detroit to become boiler-room engineer with The Detroit Edison Company, and has been employed continuously by that Company to the present time, with the exception of a year's leave of absence for war service in 1918.

In the course of this employment he has organized and directed the various engineering projects which his company has accomplished in the last twenty years, notably the design and construction of its electric power plants, Trenton Channel, Marysville, Delray No. 3, and Conners Creek. In addition to supervising new construction, Mr. Parker has also general responsibility for the operation of The Detroit Edison electrical system and of its generating plants, and central-heating plants and system.

During the first World War he served in the Nitrate Division of the Ordnance Department, United States Army, as consulting mechanical engineer and head of that Division's inspection section.

He served ten years as a Trustee of Cornell University, elected by the alumni in 1929 and re-elected in 1934.

Mr. Parker has been a member of The American Society of Mechanical Engineers since 1913. From 1928 to 1933 he served as member of the Committee on Meetings and Program, and as Manager from 1935 to 1938, and Vice-President from 1938 to 1940. He served as a member of the Society's executive committee for four years.

He served a three-year term (1938-1941) as president of the Engineering Society of Detroit, of which he has been a director since the organization of the new society in 1936; and is a member of the Michigan Engineering Society and the Prismatic Club of Detroit.

The American Society of Mechanical Engineers

HEADQUARTERS: 29 West 39th St., New York, N. Y.

C. I. Rainesale
MacDonald S. Reed
A. F. Wild

FLORIDA

Organized: 1925
Territory: State of Florida
Place of Meeting: Various Cities in State
Local Organization: Florida Engineering Society, Gainesville, Fla.
Number of Members: 82

Executive Committee

V. C. Couchman, *Chairman*
W. E. Drew, *First Vice-Chairman*
John Hunter, *Second Vice-Chairman*
C. F. Whitcomb, Jr., *Secretary-Treasurer*
T. H. Gardner
R. A. Thompson
E. P. Wood
R. R. Roberts, *Student-Chairman*

FORT WAYNE

Organized: 1939
Territory: Counties of LaGrange, Steuben, Noble, DeKalb, Whitley, Allen, Wabash, Huntington, Wells, Adams, Miami, Blackford and Jay in Indiana; Counties of Williams, Defiance, Paulding, Van Wert and Mercer in Ohio
Local Organization: Fort Wayne Engineers' Society
Number of Members: 30

Executive Committee

F. L. Ruoff, *Chairman*
F. T. McInerney, Jr., *Vice-Chairman*
K. K. Cooper, *Secretary*
W. H. Connor, *Treasurer*
N. T. Bourke
W. L. Knauss

GREEN MOUNTAIN

Organized: 1923
Territory: Entire State of Vermont and neighboring and closely related communities of Claremont and Hanover, N.H.
Place of Meeting: Springfield, Windsor, Vt., and Claremont, N.H.
Local Organization: Vermont Engineering Society
Number of Members: 37

Executive Committee

C. H. Adams, *Chairman*
F. T. Gear, *Vice-Chairman*
F. A. Johnson, *Secretary-Treasurer*
E. D. Clark
H. L. Daasch
D. T. Hamilton
J. B. Johnson

GREENVILLE

Organized: As a Branch, 1923; as a Section, 1927
Territory: Radius of sixty miles from Greenville, S.C.
Place of Meeting: Meetings held at Greenville, Clemson College, S.C., Canton, Asheville, and Enka, N.C.
Number of Members: 46

Executive Committee

J. W. Vaughan, Jr., *Chairman*
C. R. Hoey, Jr., *Vice-Chairman*
J. E. Waldrep, *Secretary-Treasurer*
J. A. McPherson
C. F. Mercer
W. P. Tindall
A. H. Vanderhoof
J. C. Whitehurst

HARTFORD

Organized: 1917, as Branch of Conn. Section; reorganized, 1923; New Britain Section merged with Hartford Section, July 1, 1940
Territory: Hartford County except that portion served by New Britain Section
Place of Meeting: Hartford Electric Light Company
Number of Members: 161

Executive Committee

H. F. Ramm, *Chairman*
Henry Michelsen, L. C. Smith } *Vice-Chairmen*
R. D. Keller, *Secretary-Treasurer*
P. W. Bauer

INLAND EMPIRE

Organized: 1921
Territory: East of Columbia River in State of Washington, and Counties of Okanogan and Benton, and part of Northern Idaho
Place of Meeting: Davenport Hotel, Spokane
Luncheons Wednesdays at 12:00 noon, Davenport Hotel, Spokane
Local Organization: Associated Engineers of Spokane
Number of Members: 20

Executive Committee

J. G. McGivern, *Chairman*
F. W. Candee, *Vice-Chairman*
N. W. Humphrey, *Secretary-Treasurer*
Alexander Lindsay
E. B. Parker
L. J. Pospisil

ITHACA

Organized: 1936
Territory: Radius of thirty miles from Ithaca plus following cities: Binghamton, Corning, Endicott, Geneva, Painted Post
Place of Meeting: Alternately in different cities of Section territory, as announced.
Number of Members: 80

Executive Committee

C. L. Wilder, *Chairman*
S. S. Garrett, *Vice-Chairman*
F. S. Erdman, *Secretary-Treasurer*
D. S. Kimball, Jr.
W. M. Sawdon
M. P. Whitney
N. P. Wickersham

KANSAS CITY

Organized: 1921
Territory: Radius of sixty miles from Kansas City, Mo.
Place of Meeting: University Club
Local Organization: Engineers' Club of Kansas City
Number of Members: 118

Executive Committee

J. R. Stone, *Chairman*
R. V. Sutherland, *Vice-Chairman*
R. P. Hahn, *Secretary*
M. A. Durland, *Treasurer*
F. R. Applegate
C. E. Brown
E. M. Bruzelius
T. C. Cheasley
H. L. Crain
R. S. Tait

Junior Group

H. W. Cockrill, *Chairman*
Jack Weisbein, *Secretary*

LOS ANGELES *

Organized: 1915
Territory: South of southern boundaries of following counties: Monterey, Kings, Tulares, and Inyo, Calif.
Place of Meeting: Barker Bros. Store
Local Organization: Technical Societies of Los Angeles
Luncheon Meetings Thursdays at 12:00 noon at Engineers' Club
Number of Members: 560

Executive Committee

J. Calvin Brown, *Chairman*
E. M. Wagner, *Vice-Chairman*
C. E. McGinnis, *Secretary-Treasurer*
P. L. Armstrong
D. K. Coyle
R. B. Esselman
J. S. Gallagher
R. G. Roshong
C. H. Shattuck
H. S. Spaulding

Junior Group

John H. Hanna, *Junior Chairman*
LeRoy Barrett, *Secretary*
W. L. Parker, *Member at Large*

San Diego Sub-Section

John L. Bacon, *Chairman*
Louis Baldo, *Secretary-Treasurer*

LOUISVILLE

Organized: 1922
Territory: Radius of thirty miles from Louisville, Ky. (includes Lexington, Ky.)
Place of Meeting: University of Louisville, Louisville, Ky.
Local Organization: Engineers and Architects Club
Number of Members: 79

Executive Committee

W. F. Lucas, *Chairman*
H. C. Murphy, *Vice-Chairman*
C. D. Greffe, *Secretary*
J. K. Meyer, *Treasurer*
O. C. Krause
L. S. O'Bannon
J. H. Roman
Melvin Sack

MEMPHIS

Organized: 1923
Territory: Radius of sixty miles from Memphis, Tenn., and eastern half of Arkansas including all the territory east of a line drawn north and south through the western boundary of the city of Little Rock
Number of Members: 23

Executive Committee

R. H. Sogard, *Chairman*
W. H. Roberts, *Vice-Chairman*
J. A. Mollino, Jr., *Secretary-Treasurer*
T. H. Allen
E. J. Kueck

METROPOLITAN

Organized: 1910
Territory: Metropolitan District, New York and New Jersey
Place of Meeting: Engineering Societies Building, 29 West 39th Street, New York, N.Y.
Number of Members: 3,184

Executive Committee

F. D. Carvin, *Chairman*
G. J. Nicastro, *Secretary*
W. H. Larkin, 3rd, *Treasurer*
H. C. R. Carlson, *Chairman of Meetings and Program Committee*
E. J. Billings
P. E. Frank
W. S. Gleeson
P. T. Onderdonk
C. B. Peck
A. R. Mumford, *Ex-Officio*

Junior Group

J. L. Hall, *Chairman*
F. H. Fowler, Jr., *Vice-Chairman*
F. M. Gibson, Jr., *Secretary*
J. S. Hunter
C. C. Kirby
R. L. Robertson
H. D. Strong

MID-CONTINENT

Organized: 1919
Territory: Entire State of Oklahoma; territory in Arkansas not included in Memphis Section; part of Louisiana; and territory in Texas north of the southern boundaries of the counties of Gaines, Dawson, Bordon, Scurry, Fisher, Jones, and Shackelford

* Name changed to Southern California, November 30, 1941.

MID-CONTINENT

(Continued)

Place of Meeting: Usually Mayo Hotel, Tulsa, Okla.
Luncheon Meetings with Engineers Club of Tulsa, Mondays at 12:00 noon
Local Organization: Engineers Club of Tulsa
Number of Members: 130

Executive Committee

E. C. Baker, *Chairman*
A. N. Horne, *Vice-Chairman*
T. C. Webb, *Secretary*
E. H. Parker, *Treasurer*
E. E. Ambrosius
R. G. Ayers
D. O. Barrett
H. B. Bernard
A. G. Blanchard
W. L. Ducker, Jr.
R. L. Feagles
W. G. Heltzel
Gwynne Raymond
W. S. Sherman
H. A. Wienecke

MILWAUKEE

Organized: 1904
Territory: Radius of fifty miles from Milwaukee, Wis.
Place of Meeting: Wisconsin Club
Local Organization: Engineers' Society of Milwaukee
Luncheon Meetings once each month, 3rd Wednesday at Wisconsin Club
Number of Members: 214

Executive Committee

T. F. Eserkaln, *Chairman*
R. J. Smith, *Secretary-Treasurer*
James Brower
H. P. Dahlstrand
F. H. Dorner, Sr.
M. K. Drewry
Walter Ferris
O. A. Kisa
J. L. Martin
R. C. Newhouse

Junior Group

J. L. Martin, *Chairman*
J. H. Stanek, *Secretary*
Harry Gute
P. J. Imse
M. E. Ruess
W. T. Saveland, Jr.
R. C. Strassman

MINNESOTA

Organized: Minneapolis, 1913; St. Paul, 1913; the two Sections merged, 1934
Territory: Entire State of Minnesota
Place of Meeting: Minnesota Union, Univ. of Minnesota
Local Organization: Minneapolis Engineers Club, Minnesota Federation of Architectural and Engineering Societies
Number of Members: 98

Executive Committee

M. S. Wunderlich, *Chairman*
L. C. Sprague, *Vice-Chairman*
N. J. Sternal, *Secretary-Treasurer*
W. H. Erskine
Charles Foster
C. A. Herrick
L. G. Straub

NEBRASKA

Organized: 1922
Territory: State of Nebraska, and Council Bluffs, Iowa
Place of Meeting: Lincoln and Omaha
Local Organization: Engineers' Clubs of Lincoln and Omaha
Luncheon Meeting every Wednesday noon at the Omaha Engineers' Club—4th Monday Evening at Lincoln
Number of Members: 33

Executive Committee

J. W. Kurtz, *Chairman*
J. W. Haney, *Vice-Chairman*
G. A. Rogers, *Secretary-Treasurer*
E. V. Perkins, *Chairman of Meetings and Program Committee*
J. K. Ludwickson
A. A. Luebs
C. F. Moulton
W. F. Weiland

NEW HAVEN

Organized: 1912, reorganized, 1923
Territory: Portions of New Haven and Middlesex Counties, Conn.
Place of Meeting: Mason Laboratory, Yale University
Number of Members: 78

Executive Committee

L. H. Von Ohlsen, *Chairman*
I. T. Hook, *Vice-Chairman*
F. C. Richardson, *Secretary-Treasurer*
D. L. Bacon
A. F. Breitenstein
G. H. Eaton
L. C. Lichty

NEW ORLEANS

Organized: 1916
Territory: All of Louisiana except the northern part allotted to Mid-Continent Section
Place of Meeting: Room 422, St. Charles Hotel
Local Organization: Louisiana Engineering Society
Number of Members: 99

Executive Committee

G. R. Hammett, *Chairman*
L. J. Cucullu, *Vice-Chairman*
A. M. Hill, *Secretary-Treasurer*
E. L. Cowan
L. J. Lassalle
J. R. Rombach, Jr.
A. D. Stancliff
D. W. Stewart

Junior Group

J. R. Rombach, Jr., *Chairman*
H. W. Voelkel, *Vice-Chairman*
G. H. Schmitt, Jr., *Secretary*

NORTH TEXAS

Organized: 1922
Territory: All of Texas north of an approximately straight line through Del Rio, Fredericksburg, Georgetown, Cameron, Nacogdoches, and center, including the cities mentioned, and south of north boundaries of the counties of Parmer, Castro, Swisher, Briscoe, Hall, and Childress. Also the City of Texarkana, Ark.
Place of Meeting: Dallas Power & Light Co. Bldg. Auditorium
Local Organization: Technical Club of Dallas
Number of Members: 101

Executive Committee

F. C. Justice, *Chairman*
J. A. Noyes, *Vice-Chairman*
E. J. Wacker, *Secretary-Treasurer*
H. E. Chambers, Jr.
H. M. Robinson
C. H. Shumaker
Ray M. Matson, *Ex-Officio*

NORWICH

Organized: 1930
Territory: Counties of Tolland, Windham, and New London in Connecticut, and Westerly District in Rhode Island
Place of Meeting: New London Junior College, Pequot Ave., New London, Conn.
Number of Members: 50

Executive Committee

A. W. Luce, *Chairman*
Robert Wosak, *Secretary-Treasurer*
W. A. Morain, *Chairman of the Program Committee*
A. D. Andriola
W. E. Beaney
W. E. Edel
F. E. English
Dana Young

ONTARIO

Organized: 1917
Territory: Province of Ontario, Canada
Place of Meeting: Hart House, University of Toronto
Number of Members: 176

Executive Committee

H. H. Angus, *Chairman*
Ernest Jones, *Secretary-Treasurer*
T. H. Blair
A. C. Blue
S. G. Clarke
C. R. Davis
H. G. Hill
T. S. Jardine
W. G. McIntosh
W. E. Micklethwaite
A. A. Moline
W. D. Sheldon
Ered'k Truman

Junior Group

W. R. Trusler, *Chairman*
J. M. Van Winckle, *Secretary-Treasurer*
C. E. Beynon
J. H. Miller
F. Taylor

OREGON

Organized: 1919
Territory: State of Oregon and that territory in Washington within a radius of thirty miles from Portland, Ore.
Place of Meeting: Usually Public Service Bldg., Portland, Ore.
Local Organization: Oregon Society of Engineers
Number of Members: 45

OREGON

(Continued)

EXECUTIVE COMMITTEE

A. A. OSIPOVICH, *Chairman*
C. GORDON TUPLING, *Vice-Chairman*
E. P. WEISER, *Secretary-Treasurer*
A. J. CHAPUT
A. D. HUGHES
TOM PERRY
R. B. ROWAN

PENINSULA

Organized: 1923
Territory: West of the east boundaries of the following counties: Emmet, Charlevoix, Antrim, Kalkaska, Missaukee, Clare, Isabell, Gratiot, Clinton, Eaton, Calhoun, and Branch, Mich.
Place of Meeting: Grand Rapids, Mich.
Luncheon Meeting Fifth Thursday noon each month
Local Organization: Engineers' Club of Grand Rapids
Number of Members: 50

EXECUTIVE COMMITTEE

JOHN M. GORRIE, *Chairman*
DONALD MCSORLEY, *1st Vice-Chairman*
KENNETH CROWSER, *2nd Vice-Chairman*
CARL J. KUENZEL, *Secretary-Treasurer*
CHARLES BUCK
JANUS R. DE HAMER
GAROLD GEBBEN
CONRAD LOHMANN
GEORGE WARING
CHARLES A. HAMILTON, *Ex-officio*

PHILADELPHIA

Organized: 1912
Territory: Counties of Bucks, Montgomery, Chester, Philadelphia, Delaware, Pa., and the State of Delaware
Place of Meeting: Philadelphia Engineers' Club, 1317 Spruce Street, Philadelphia, Pa.
Local Organization: Philadelphia Engineers' Club
Luncheon Meeting every Thursday noon at 12:30 p.m. at Philadelphia Engineers' Club
Number of Members: 1,002

EXECUTIVE COMMITTEE

J. STANLEY MOREHOUSE, *Chairman*
C. S. GOTWALS, *Vice-Chairman*
L. N. GULICK, *Secretary-Treasurer*
L. P. HYNES
J. J. MCCARTHY
F. W. MILLER

J. P. CLARK
T. M. POMEROY, JR.
N. R. SEFING
R. D. STAFFER

PIEDMONT—NORTH CAROLINA

Organized: As a Branch, 1923; as a Section 1927; name changed from Charlotte Section to Piedmont—North Carolina, July 1, 1940
Territory: Radius of seventy-five miles from Charlotte, N.C.
Luncheon Meeting every other Monday at 1:00 p.m. at Efirds Department Store Dining Room
Local Organization: Charlotte Engineers Club
Number of Members: 46

EXECUTIVE COMMITTEE

R. W. OLIVE, *Chairman*
A. B. LECLERC, *Vice-Chairman*
W. B. FREEMAN, *Secretary-Treasurer*
B. L. COTTON
C. A. DEWEY
I. W. LEGGETT
R. P. REECE
T. O. SILLS

PITTSBURGH

Organized: 1920
Territory: Counties bounded by and including Beaver, Butler, Venango, Forest, Jefferson, Indiana, Somerset, Fayette, Greene, and Washington, Pa.
Place of Meeting: Engineers' Society of Western Pennsylvania, William Penn Hotel
Local Organization: Engineers' Society of Western Pennsylvania
Number of Members: 423

EXECUTIVE COMMITTEE

L. N. SHARANBERG, *Chairman*
T. J. BARRY, *Vice-Chairman*
C. A. HAHN, *Secretary*
K. F. TRESCHOW, *Treasurer*
S. B. ELY
J. N. EVANS
H. H. HALL
H. L. PARLETTE
R. E. PETERSON
KENNETH SEAVER
J. R. TANNER

PLAINFIELD

Organized: 1921
Territory: Plainfield and territory included between Elizabeth, Bound Brook, Metuchen, and Watchung, N.J.
Place of Meeting: Elizabeth Carteret Hotel, Elizabeth, and Plainfield Masonic Temple, Plainfield
Local Organization: Plainfield Engineers Club, Singer Engineering Society
Number of Members: 170

EXECUTIVE COMMITTEE

G. E. LEAVITT, JR., *Chairman*
F. C. SPENCER, JR., *Vice-Chairman*
E. E. FRANZ, *Secretary*
C. G. HOLMBERG, *Treasurer*
R. C. HECK, JR.
K. A. REEVE

PROVIDENCE

Organized: 1920
Territory: Radius of thirty miles from Providence, R.I.
Place of Meeting: Providence Engineering Society Building, 195 Angell St., Providence, R.I.
Local Organization: Providence Engineering Society
Number of Members: 159

EXECUTIVE COMMITTEE

J. D. ELDERT, *Chairman*
J. D. ROBERTSON, *Vice-Chairman*
R. M. SCOTT, *Secretary-Treasurer*
C. D. BILLMEYER
A. W. CALDER, JR.
J. S. CHAFEE
E. W. HARRINGTON
A. WILLIAM MEYER
P. V. MILLER
A. JOEL WARREN
G. E. WHEELER, JR.

RALEIGH

Organized: As a Branch, 1923; as a Section, 1927
Territory: Radius of sixty miles from Raleigh, N.C.
Places of Meeting: North Carolina State College, Raleigh, N.C.; Duke University, Durham, N.C.
Local Organizations: North Carolina Society of Engineers, Raleigh Engineers Club
Number of Members: 33

EXECUTIVE COMMITTEE

R. B. RICE, *Chairman*
F. B. TURNER, *Vice-Chairman*
R. G. CHAPMAN, *Secretary-Treasurer*
E. G. HOEFER
C. E. KERCHNER
R. M. ROTHGEB
R. S. WILBUR

ROCHESTER

Organized: 1919
Territory: Radius of thirty miles from Rochester, N.Y.
Place of Meeting: Rochester Engineering Society Rooms, Sagamore Hotel
Local Organization: Rochester Engineering Society, Sagamore Hotel
Luncheon Meeting every Tuesday at 12:15 p.m. at Sagamore Hotel
Number of Members: 109

EXECUTIVE COMMITTEE

I. S. BRADLEY, *Chairman*
W. D. WOOD, *Vice-Chairman*
I. G. MCCHESNEY, *Secretary-Treasurer*
K. H. HUBBARD
F. D. PUNNETT
A. E. SCHELL
A. W. SCHUSTER
J. H. SNYDER

ROCK RIVER VALLEY

Organized: 1926
Territory: Thirty miles east and west of Madison, Wis., and extending southward through Rockford, Ill.
Meeting Places: Madison, Wis., Beloit, Wis., and Rockford, Ill.
Local Organization: Rock River Valley Engineering Council
Number of Members: 73

EXECUTIVE COMMITTEE

C. A. JACOBSON, *Chairman*
B. G. ELLIOTT, *Vice-Chairman*
E. L. DAHLUND, *Secretary-Treasurer*
C. L. AVERY
M. W. DUNDORE
D. W. NELSON
F. J. ZIRCHER

ST. JOSEPH VALLEY

Organized: 1929
Territory: Counties of La Porte, Starke, Pulaski, St. Joseph, Marshall, Fulton, Elkhart, and Kosciusko in Indiana, and Cass and Berrien Counties in Michigan
Place of Meeting: South Bend, Ind.
Number of Members: 47

ST. JOSEPH VALLEY

(Continued)

EXECUTIVE COMMITTEE

E. J. WILLIAMS, *Chairman*
E. T. COBB, L. E. WADDINGTON, O. E. ZAHN } *Vice-Chairmen*
K. W. KNORR, *Secretary*
H. E. HOLLENSBE
J. A. MACLEAN
W. D. A. PEASLEE
L. E. WADDINGTON
C. C. WILCOX

ST. LOUIS

Organized: 1909
Territory: Radius of thirty miles from St. Louis, Mo.
Place of Meeting: Place varies
Local Organization: Engineers' Club of St. Louis
Number of Members: 205

EXECUTIVE COMMITTEE

R. W. MERKLE, *Chairman*
R. C. THUMSER, *Vice-Chairman*
HERBERT KUENZEL, *Secretary-Treasurer*
C. B. BRISCOE, *Chairman of the Program Committee*

SAN FRANCISCO

Organized: 1910
Territory: All territory north of the northern boundaries of the counties of San Luis Obispo, Kern, and San Bernardino
Place of Meeting: Engineers' Club, 206 Sansome St.
Luncheon Meetings, Tuesdays, California Hotel, Oakland; Thursdays, Engineers' Club, San Francisco
Local Organization: San Francisco Engineers' Club
Number of Members: 387

EXECUTIVE COMMITTEE

H. T. AVERY, *Chairman*
G. N. SOMERVILLE, *Vice-Chairman*
E. H. CAMERON, *Secretary-Treasurer*

W. B. PRESTON
J. G. H. THOMPSON
M. W. WILLIAMS

SUSQUEHANNA

Organized: 1927
Territory: Counties of Cumberland, Dauphine, Lebanon, Adams, York, and Lancaster
Place of Meeting: Engineering Society of York, and at Lancaster Twice a Year
Local Organization: Engineering Society of York and Engineers' Society of Pennsylvania, Harrisburg, Pa.
Number of Members: 76

EXECUTIVE COMMITTEE

O. E. WEBER, *Chairman*
S. P. SOLING, *Vice-Chairman*
E. T. P. NEUBAUER, *Secretary-Treasurer*
T. K. BREDA
JACOB FISCH
M. G. LEESON
M. E. SILBERGER

SYRACUSE

Organized: 1920
Territory: Radius of thirty miles from Syracuse, N.Y.
Place of meeting: Ball Room of the Onondaga Hotel
Local Organization: The Technology Club of Syracuse
Number of Members: 89

EXECUTIVE COMMITTEE

D. V. SHETLAND, *Chairman*
M. F. WILLIAMS, *Vice-Chairman*
E. A. FAILMEZGER, *Secretary-Treasurer*
L. E. POTTER, *Assistant Secretary*
H. T. AVERY
C. F. DIETZ
E. R. JEFFERSON
J. W. LINFORD

R. H. MARKER
W. R. MORAN
R. J. MUGFOR
L. S. PLATOU
JOSEPH SEAMAN

TRI-CITIES

Organized: 1920
Territory: Radius of thirty miles from Moline, Ill.
Place of Meeting: Rock Island, Ill., Moline, Ill., and Davenport, Iowa
Luncheon Meeting every Wednesday, Davenport Hotel, 12:00 noon
Number of Members: 76

EXECUTIVE COMMITTEE

R. A. CROSS, *Chairman*
E. G. ERICKSON, *Vice-Chairman*
C. A. CARLSON, *Secretary-Treasurer*
P. E. ANDERSON
R. M. BARNES
K. R. HODGES

UTAH

Organized: 1923
Territory: State of Utah
Place of Meeting: University Club, Salt Lake City
Local Organization: Utah Society of Professional Engineers
Number of Members: 33

EXECUTIVE COMMITTEE

G. W. CARTER, *Chairman*
G. M. JONES, *Vice-Chairman*
R. D. BAKER, *Secretary-Treasurer*
C. B. BOWMAN
W. J. COPE
W. D. TURPIN

VIRGINIA

Organized: 1919
Territory: State of Virginia
Place of Meeting: Richmond, Norfolk, Blacksburg, Charlottesville, Roanoke, University, Petersburg
Local Organization: Central Virginia Engineers Club of Hampton Roads
Number of Members: 200

Executive Committee

G. C. Molleson, *Chairman*
J. B. Jones, *Vice-Chairman*
F. S. Roop, Jr., *Secretary*
W. J. Barber, *Treasurer*
G. L. Bascome
H. C. Hesse
H. R. Hopkins
M. L. Ireland, Jr.
Arthur Roberts, Jr.
H. C. Wintzer

WASHINGTON, D.C.

Organized: 1919
Territory: District of Columbia
Place of Meeting: Auditorium, Potomac Electric Power Co., 10th & E Sts., Washington, D.C.
Number of Members: 337

Executive Committee

W. B. Ensinger, *Chairman*
J. W. Huckert, *Vice-Chairman*
M. A. Mason, *Secretary-Treasurer*
C. E. Miller
T. R. Tate
J. E. Younger
G. F. Jenks, *Ex-Officio*

Junior Group

J. C. Phillips, *Chairman*
H. R. Booth
E. J. H. Lane
R. C. Meleney
F. M. Thuney
R. V. Vittucci

WATERBURY

Organized: 1917, as a Branch; reorganized as a Section, 1923
Territory: Litchfield County and a portion of New Haven County
Place of Meeting: Elton Hotel
Number of Members: 63

Executive Committee

A. L. Alves, *Chairman*
J. R. Hicks, *Vice-Chairman*
H. C. Ashley, *Secretary-Treasurer*
P. E. Peterson
W. C. Schneider
R. W. Shoemaker
R. S. Storrs

WESTERN MASSACHUSETTS

Organized: 1922
Territory: Includes counties of Berkshire, Franklin, Hampden, and Hampshire
Place of Meeting: Highland Hotel, Springfield, Mass.
Local Organization: Engineering Society of Western Massachusetts
Number of Members: 86

Executive Committee

C. Frank Dupee, *Chairman*
R. A. Packard, *Vice-Chairman*
D. A. Bartlett, *Secretary-Treasurer*
A. E. Benson
J. F. Malcolm
E. Lovell Smith

WESTERN WASHINGTON

Organized: 1919
Territory: State of Washington west of Columbia River with exception of territory included in 30-mile radius of Portland, Ore.
Place of Meeting: Engineers' Club, Seattle, Wash.
Local Organization: Seattle Engineers' Club
Luncheon Meetings daily at noon at Engineers' Club, Seattle
Number of Members: 168

Executive Committee

C. B. Shovar, *Chairman*
R. H. G. Edmonds, *Vice-Chairman*
S. Dan Hage, *Secretary-Treasurer*
R. E. Johnson
H. C. Krehbiel, Jr.
J. E. Mylroie

WEST VIRGINIA

Organized: 1925
Territory: State of West Virginia, South of Parallel 39
Place of Meeting: Charleston, W.Va.
Number of Members: 58

Executive Committee

A. H. Cannon, *Chairman*
J. Gilbert Miller, *Vice-Chairman*
J. L. Barker, Jr., *Secretary-Treasurer*
M. S. Bloomsburg
Minott Brooke
C. B. Cochran
H. C. Lewis

WORCESTER

Organized: 1915
Territory: Radius of thirty miles from Worcester, Mass.
Place of Meeting: Sanford Riley Hall, Worcester Poly. Inst.
Local Organization: Worcester Engineering Society
Number of Members: 130

Executive Committee

H. P. Crane, *Chairman*
G. H. MacCullough, *Vice-Chairman*
E. W. Armstrong, *Secretary-Treasurer*
L. R. Ball, *Chairman of Program Committee*
E. K. Allen, Jr.
J. A. Henrickson
F. R. Jones
C. M. McMahon
F. W. Naughton, Jr.
W. M. Wilcox

YOUNGSTOWN

Organized: 1928
Territory: Counties of Trumbull, Mahoning, and Columbiana in Ohio, and Mercer and Lawrence in Pennsylvania
Place of Meeting: Republic Rubber Co. Club Rooms, Albert St., Youngstown, Ohio
Number of Members: 55

Executive Committee

H. W. Smith, *Chairman*
L. A. Kline, *Vice-Chairman*
C. W. Foard, *Secretary-Treasurer*
F. J. Bowers
C. H. Legler
W. J. Longacher
H. E. Melin

STUDENT BRANCHES

ARTICLE B6A, PAR. 20: The Standing Committee on Relations With Colleges shall, under the direction of the Council, have supervision of the Student Branches of the Society and of such work of the Society as aims to further the education of engineers through the colleges and schools of accepted standing.

STANDING COMMITTEE, RELATIONS WITH COLLEGES

A. C. CHICK, *Chairman* (1942)
J. I. YELLOTT (1943)
H. E. DEGLER (1944)
G. L. SULLIVAN (1945)
R. P. REECE (1946)

J. W. HANEY, B. T. MCMINN, R. H. PORTER } *Advisory Members* (1942)

J. L. HALL, *Junior Adviser* (1942)

† As of December 15, 1941. * Faculty Adviser.

RESEARCH COMMITTEES

ARTICLE B6A, PAR. 24: The Standing Committee on Research shall, under the direction of the Council, have supervision of the research activities of the Society.

The first Standing Committee on Research was organized in 1909.

STANDING COMMITTEE

W. TRINKS, *Chairman* (1942)
M. D. HERSEY (1943)
HERMAN WEISBERG (1944)
W. R. ELSEY (1945)
J. F. D. SMITH (1946)

LUBRICATION

Appointed October, 1915, to investigate the fundamental problems of lubrication, to formulate results of investigations previously made, and to keep in touch with contemporary research in this field

(Reorganized May, 1936)

G. B. KARELITZ, *Chairman*
S. J. NEEDS, *Secretary*
A. L. BEALL
OSCAR BRIDGEMAN
W. E. CAMPBELL
H. A. EVERETT
A. E. FLOWERS
J. C. GENIESSE
RAYMOND HASKELL
M. D. HERSEY
B. F. HUNTER
C. M. LARSON
F. C. LINN
G. L. NEELY
B. L. NEWKIRK
E. S. PEARCE
ERNEST WOOLER

FLUID METERS

Appointed 1916 to develop the theory of fluid meters of all kinds and to report on the best methods for their installation and use

(Reorganized July, 1926)

R. J. S. PIGOTT, *Chairman*
J. R. CARLTON, *Secretary*
H. S. BEAN
S. R. BEITLER
R. K. BLANCHARD
B. O. BUCKLAND
LOUIS GESS
E. W. JACOBSON
A. J. KERR
T. H. KERR
M. P. O'BRIEN
W. S. PARDOE
L. K. SPINK
R. E. SPRENKLE
E. C. M. STAHL
T. R. WEYMOUTH
M. J. ZUCROW

THERMAL PROPERTIES OF STEAM

Appointed in December, 1921, to direct research on the thermal properties of water-vapor and steam from 0 C to the upper limits of temperature and pressure

(Reorganized April, 1929)

W. L. ABBOTT, *Vice-Chairman*
H. N. DAVIS
H. C. DICKINSON
A. M. GREENE, JR.
R. C. H. HECK
D. S. JACOBUS
MAX JAKOB
J. H. KEENAN
F. G. KEYES
L. S. MARKS
GEO. A. ORROK
R. J. S. PIGOTT
E. L. ROBINSON

STRENGTH OF GEAR TEETH

Appointed in December, 1921, to investigate factors affecting the strength and life of gear teeth

R. E. FLANDERS, *Chairman*
C. H. LOGUE, *Secretary*
EARLE BUCKINGHAM
A. M. GREENE, JR.
C. W. HAM
F. E. McMULLEN
E. W. MILLER
ERNEST WILDHABER

CUTTING OF METALS

Appointed in September, 1923, to study the problems of metal cutting, including tool materials, tool design, lubrication, cooling, and speeds and feeds

M. F. JUDKINS, *Chairman*
L. N. GULICK, *Secretary*
L. P. ALFORD *
O. W. BOSTON
R. C. DEALE
A. L. DELEEUW
C. M. THOMPSON, JR.

MECHANICAL SPRINGS

Appointed May, 1924, to determine the status of the mechanical-spring art, to promote and conduct necessary and adequate research, and to develop the art to the point of standardization

J. R. TOWNSEND, *Chairman*
C. T. EDGERTON, *Secretary*
R. W. COOK
W. T. DONKIN
RUPEN EKSERGIAN
G. E. HANSEN
BENJAMIN LIEBOWITZ
DAVID LOFTS
R. D. BRIZZOLARA (*Alternate*)
D. J. McADAM, JR.
L. C. PESKIN
R. E. PETERSON
J. W. ROCKEFELLER, JR.
B. W. ST. CLAIR
M. F. SAYRE
T. R. WEBER
KEITH WILLIAMS
J. K. WOOD
F. P. ZIMMERLI

ELEVATORS

Appointed June, 1924, to study the function and operation of elevator safeties and buffers and their associated mechanisms and to develop methods of test for the approval of elevator safety devices

(Reorganized August, 1940)

D. J. PURINTON, *Chairman*
D. L. LINDQUIST, *Vice-Chairman*
G. H. REPPERT (*Alternate*)
J. A. DICKINSON, *Secretary*
S. W. JONES, *Ex-officio*
E. M. BOUTON
E. B. DAWSON (*Alternate*)
K. A. COLAHAN
G. P. KEOGH
F. PAVLICEK (*Alternate*)
J. J. MATSON
M. B. McLAUTHLIN
C. R. CALLAWAY (*Alternate*)
W. S. PAINE
J. L. KEANE (*Alternate*)
C. A. PETERS, JR.

EFFECT OF TEMPERATURE ON THE PROPERTIES OF METALS

Appointed December, 1924, as a joint research committee of the A.S.T.M. and the A.S.M.E. to encourage the investigation and accumulation of data on the properties of metals used in the mechanic arts at extremely high and low temperatures

N. L. MOCHEL, *Chairman*
H. J. KERR, *Vice-Chairman*
J. W. BOLTON, *Secretary*
R. H. ABORN
W. H. ARMACOST
A. B. BAGSAR
A. D. BAILEY
F. E. BASH
C. L. CLARK
E. S. DIXON
F. B. FOLEY
J. R. FREEMAN, JR.
H. J. FRENCH
H. W. GILLETT
A. J. HERZIG
G. F. JENKS
J. J. KANTER
C. E. MACQUIGG
E. L. ROBINSON
A. E. WHITE
J. S. WORTH
Director, National Bureau of Standards, U.S. Department of Commerce
Representative of Bureau of Ships, U.S. Navy Department

BOILER FEEDWATER STUDIES

Appointed March, 1925, as a Joint Research Committee of the American Boiler Manufacturers Association, American Railway Engineering Association, American Water Works Association, Edison Electric Institute, the American Society for Testing Materials, and the A.S.M.E. to study methods of analysis and treatment of boiler feedwater for stationary and railroad practice

EXECUTIVE COMMITTEE (Total personnel 41)

C. H. FELLOWS, *Chairman*
R. C. BARDWELL, *Vice-Chairman*
J. B. ROMER, *Secretary*
A. G. CHRISTIE **
R. E. COUGHLIN
B. W. DE GEER
MAX HECHT
H. E. JORDAN
P. B. PLACE
S. T. POWELL
F. N. SPELLER
M. F. STACK

* Deceased, January 2, 1942.
** Official A.S.M.E. representative serving on this committee.

BOILER FEEDWATER STUDIES

(Continued)

G. E. TATE
E. H. TENNEY
A. E. WHITE *

CONDENSER TUBES

Appointed May, 1925, to investigate and report on the causes of failure of tubes used in steam condensers and similar heat interchange apparatus

A. E. WHITE, *Chairman*
D. C. WEEKS, *Vice-Chairman*
P. A. BANCELL
R. A. BOWMAN
D. K. CRAMPTON
C. A. CRAWFORD
H. M. CUSHING
R. E. DILLON
J. R. FREEMAN, JR.
V. M. FROST
C. F. HARWOOD
G. C. HOLDER
W. C. HOLMES
W. B. PRICE
J. S. RODGERS
M. F. STACK
W. R. WEBSTER
Director, Bureau of Ships, U.S. Navy Department

WORM GEARS

Appointed May, 1927, to investigate certain problems in connection with the action of worm gear drives and to recommend improvements in their design, manufacture, and use

EARLE BUCKINGHAM, *Chairman*
G. H. ACKER
L. R. BUCKENDALE
D. L. LINDQUIST
A. A. ROSS
B. F. WATERMAN
Representative of Bureau of Ships, U.S. Navy Department

STRENGTH OF VESSELS UNDER EXTERNAL PRESSURE

Appointed June, 1929, to develop reliable design data on the strength of cylindrical and spherical surfaces under external pressure, particularly with reference to jacketed vessels

F. V. HARTMAN, *Chairman*
W. D. HALSEY
M. B. HIGGINS
A. W. LIMONT, JR.
H. E. SAUNDERS
E. E. SHANOR
D. B. WESSTROM
F. S. G. WILLIAMS
D. F. WINDENBURG

WIRE ROPE

Appointed April, 1930, to investigate existing rope so that it may be better understood and more effectively used

W. H. FULWEILER, *Chairman*
H. LER. BRINK
D. L. LINDQUIST
G. W. MARTIN
A. H. MCDOUGALL
B. V. E. NORDBERG
W. S. PAINE
W. J. RYAN
GEORGE SIMPSON
L. E. YOUNG

* Official A.S.M.E. representative serving on this committee.

CRITICAL PRESSURE STEAM BOILERS

Appointed June, 1931, to study the characteristics of high-pressure forced-circulation steam-generating units

H. L. SOLBERG, *Chairman*
W. H. ARMACOST
A. D. BAILEY
E. G. BAILEY
F. S. CLARK
C. H. FELLOWS
H. J. KERR
G. A. OREOK
E. C. PETRIE
E. L. ROBINSON
P. W. THOMPSON

COTTONSEED PROCESSING

Appointed December, 1932, to study the mechanical problems involved in storing, conditioning, and cooking cottonseed meats

W. R. WOOLRICH, *Chairman*
HOMER BARNES
C. E. GARNER
J. F. LEAHY
R. W. MORTON
B. J. SAMS
R. B. TAYLOR

ROLLING OF STEEL (PLASTICITY)

Appointed October, 1938, to study plasticity in the particular field of rolling of steel

A. NADAI, *Chairman*
C. W. MACGREGOR, *Secretary*
E. C. BAIN
C. L. EKSERGIAN
J. H. HITCHCOCK
G. B. KARELITZ
MORRIS STONE
W. TRINKS

FURNACE PERFORMANCE FACTORS

Appointed in October, 1941, to collect and rationalize data on the performance of commercially important furnaces as an aid to design and operation

A. R. MUMFORD, *Chairman*
ALEX D. BAILEY
JOHN BLIZARD
S. P. BURKE
O. F. CAMPBELL
W. A. CARTER
B. J. CROSS
T. B. DREW
F. G. ELY
A. C. FIELDNER
J. H. HARLOW
H. C. HOTTEL
E. L. LINDSETH
W. H. MCADAMS
PERCY NICHOLLS
E. B. POWELL
A. A. RAYMOND
R. A. SHERMAN
PHILIP SPORN
HERMAN WEISBERG
W. J. WOHLENBERG

FORGING OF STEEL SHELLS

Appointed in October, 1941, to study methods of shell manufacture under modern conditions

M. D. STONE, *Chairman*
W. TRINKS, *Vice-Chairman*
JOHN DIERBECK
D. W. FLETCHER
W. M. FRAME
W. N. HOWLEY
A. F. MACCONOCHIE
F. C. MACDONALD
A. NADAI
GEORGE SACHS
A. E. VAN CLEVE
U. S. Army, Ordnance Department:
LT.-COL. H. U. WAGNER
MAJOR J. H. FRYE
MAJOR R. M. WOOD
U. S. Navy, Bureau of Ordnance:
LT.-COM. A. H. BATEMAN

A.S.M.E. Representatives on Other Research Committees

AMERICAN COORDINATING COMMITTEE ON CORROSION

American Society for Testing Materials

S. L. KERR
C. H. FELLOWS (*Alternate*)

CORROSION COMMITTEE

American Society of Refrigerating Engineers

(To be appointed)

FATIGUE PHENOMENA OF METALS

American Society for Testing Materials

C. T. EDGERTON

HEAT-TREATMENT OF ROCK DRILL STEELS

Advisory Board of the National Bureau of Standards and Bureau of Mines

(To be appointed)

METALLURGICAL RESEARCH

Advisory Committee to the National Bureau of Standards

C. H. BIERBAUM

PROPERTIES OF REFRACTORY MATERIALS

Advisory Committee to the National Bureau of Standards

E. B. POWELL

WATER FOR INDUSTRIAL USES

American Society for Testing Materials

J. H. WALKER

STANDARDIZATION COMMITTEES

ARTICLE B6A, PAR. 23: The Standing Committee on Standardization shall advise the Council on the dimensional standardization work of the Society, including relations with the American Standards Association.

The first Standing Committee on Standardization was organized in April, 1911

STANDING COMMITTEE

J. E. LOVELY, *Chairman* (1942)
L. T. KNOCKE (1943)
T. E. FRENCH (1944)
W. H. HILL (1945)
J. H. TAYLOR (1946)

STANDARDIZATION AND UNIFICATION OF SCREW THREADS (B1)

* *Joint sponsorship with the Society of Automotive Engineers. Sectional Committee originally organized in June, 1921. Reorganized in February, 1929*

A.S.M.E. Members (Total personnel, 36)

R. E. FLANDERS, *Chairman* †
A. M. HOUSER, *Vice-Chairman* †
EARLE BUCKINGHAM, *Secretary*
E. J. BRYANT
G. S. CASE
T. G. CRAWFORD
H. C. E. MEYER
P. V. MILLER †
W. C. MUELLER
R. H. PERRY
G. T. TRUNDLE

SUBCOMMITTEE CHAIRMEN

Special Subcommittee on Revision of American Standard, P. V. MILLER
No. 1 on Scope, Arrangement, and Editing of American National Standard, R. E. FLANDERS
No. 4 on Acme and Other Similar Threads, Except Gages, EARLE BUCKINGHAM
No. 5 on Screw Thread Gages and Inspection, G. S. CASE
No. 6 on Threading of General Purpose Nuts, J. S. DAVEY
No. 7 on Screw Threads for High Temperature Bolting, W. H. GOURLIE

PIPE THREADS (B2)

* *Joint sponsorship with the American Gas Association. Sectional Committee originally organized in 1913. Reorganized May, 1927*

A.S.M.E. Members (Total personnel, 45)

A. S. MILLER, *Chairman*
C. B. LEPAGE, *Acting Secretary*
A. F. BREITENSTEIN †
E. J. BRYANT
C. S. COLE
E. S. CORNELL, JR.
J. J. CROTTY
A. P. DENTON
J. J. HARMAN
A. M. HOUSER †
P. V. MILLER †
F. H. MOREHEAD
W. C. MORRIS
S. F. NEWMAN
L. N. SHANNON
FRANK THORNTON, JR.
J. H. WILLIAMS

SUBCOMMITTEE CHAIRMEN

No. 1 on Editing and Gaging, A. M. HOUSER
No. 2 on Taper Pipe Threads, S. B. TERRY
No. 3 on Straight Pipe Threads, A. S. MILLER
No. 4 on Plumbers' Threads, A. F. BREITENSTEIN
No. 5 on Screw Threads for Rigid Steel Conduit, JAMES BARTON
No. 6 on Special Threads for Thin Tubes, C. C. WINTER
Special Subcommittee on Tolerances on Thread Elements, E. J. BRYANT
Special Editing Subcommittee on Taper Pipe Threads, S. B. TERRY
Special Editing Subcommittee on Straight Pipe Threads, P. V. MILLER
Special Subcommittee on Truncation, E. J. BRYANT

BALL AND ROLLER BEARINGS (B3)

* *Joint sponsorship with the Society of Automotive Engineers. Sectional Committee organized December, 1920*

A.S.M.E. Members (Total personnel, 20)

W. P. KENNEDY, *Vice-Chairman* †
D. E. BATESOLE †
L. A. CUMMINGS
O. H. DORER
F. G. HUGHES
G. E. HULSE †
W. L. ILIFF †
L. F. NENNINGER
S. M. WECKSTEIN †
ERNEST WOOLER

ALLOWANCES AND TOLERANCES FOR CYLINDRICAL PARTS AND LIMIT GAGES (B4)

* *Sole sponsorship. Sectional Committee originally organized in June, 1920. Reorganized in September, 1930*

A.S.M.E. Members (Total personnel, 40)

J. E. LOVELY, *Chairman* †
F. E. BANFIELD, JR.
F. S. BLACKALL, JR.
E. J. BRYANT
EARLE BUCKINGHAM †
F. H. COLVIN †
T. G. CRAWFORD
R. E. W. HARRISON
F. O. HOAGLAND
N. E. JACOBI
H. C. E. MEYER
P. V. MILLER
W. C. MUELLER
E. C. PECK †
R. H. PERRY
W. C. SCHOENFELDT
C. C. STEVENS
G. T. TRUNDLE

SUBCOMMITTEE CHAIRMAN

No. 1 on Tolerance Systems, R. E. W. HARRISON

SMALL TOOLS AND MACHINE TOOL ELEMENTS (B5)

* *Joint sponsorship with the National Machine Tool Builders' Association, and the Society of Automotive Engineers. Sectional Committee organized September, 1922*

A.S.M.E. Members (Total personnel, 33)

W. C. MUELLER, *Chairman* †
F. O. HOAGLAND, *Vice-Chairman*
J. B. ARMITAGE
O. W. BOSTON
E. J. BRYANT
EARLE BUCKINGHAM
F. H. COLVIN †
S. A. EINSTEIN
H. E. HARRIS †
JOHN HAYDOCK
J. P. LAUX †
J. E. LOVELY
A. F. MURRAY †
ERIK OBERG
FRANK THORNTON, JR.

TECHNICAL COMMITTEES

EXECUTIVE COMMITTEE

A.S.M.E. Members (Total personnel, 5)

W. C. MUELLER, *Chairman* †
F. O. HOAGLAND, *Vice-Chairman*
H. E. HARRIS †

No. 1 ON T-SLOTS

A.S.M.E. Members (Total personnel, 6)

ERIK OBERG, *Chairman*
J. B. ARMITAGE
HARRY CADWALLADER, JR.
S. A. EINSTEIN
F. O. HOAGLAND

No. 2 ON TOOL-POSTS AND TOOL SHANKS

A.S.M.E. Members (Total personnel, 8)

O. W. BOSTON, *Chairman*
F. S. BLACKALL, JR.
GRANGER DAVENPORT
M. E. LANGE

No. 3 ON MACHINE TAPERS

A.S.M.E. Members (Total personnel, 21)

E. J. BRYANT, *Chairman*
C. B. LEPAGE, *Acting Secretary*
J. B. ARMITAGE
F. S. BLACKALL, JR.
EARLE BUCKINGHAM
F. H. COLVIN †
J. B. DILLARD
(T. F. GITHENS, *Alternate*)
B. P. GRAVES
H. E. HARRIS †
F. O. HOAGLAND
J. H. HORIGAN
L. F. NENNINGER

SUBGROUP CHAIRMEN

Steep Tapers Series, S. MCMULLAN
Revision on Slow Taper Standard, E. J. BRYANT

* Note: All of these standards committees for which the Society is sponsor or joint sponsor, or on which it has representation, are organized under the procedure of the American Standards Association.

† Official A.S.M.E. representative serving on this committee.

SMALL TOOLS AND MACHINE TOOL ELEMENTS (B5)

(Continued)

No. 4 on Spindle Noses and Collets for Machine Tools

A.S.M.E. Members (Total personnel, 26)

J. E. Lovely, *Chairman*
L. F. Nenninger, *Secretary*
J. B. Armitage
B. P. Graves
F. O. Hoagland
A. M. Johnson
M. E. Lange
J. H. Mansfield
L. D. Spence

SUBGROUP CHAIRMEN

No. 1 on Milling Machines, Small and Medium, J. B. Armitage
No. 2 on Large Milling Machines, F. B. Kampmeier
No. 3 on Grinding Machine Spindles, H. J. Griffing
No. 5 on Drilling Machines and Horizontal Boring Machines, S. McMullan
No. 6 on Turning Machines, Including Automatic Screw Machines, Lathes, Automatic Lathes, Turret Lathes, and Automatic Chucking Machines, J. E. Lovely
No. 8 on Correlation of Counter Proposals for Spindle Noses, J. E. Lovely

No. 5 on Milling Cutters

A.S.M.E. Members (Total personnel, 20)

J. B. Armitage
A. N. Goddard
J. H. Horigan
G. L. Markland, Jr.
E. K. Morgan
Erik Oberg
E. D. Vancil

SUBGROUP CHAIRMEN

No. 1 on Profile Cutters, E. D. Vancil
No. 2 on Keyways, J. B. Armitage
No. 3 on Nomenclature, A. C. Danekind
No. 4 on Limits, J. H. Horigan
No. 5 on Formed Cutters, H. C. Hungerford
No. 6 on Hobs, G. L. Markland, Jr.
No. 7 on Inserted Tooth Cutters, J. B. Armitage

No. 6 on Designations and Working Ranges of Machine Tools

A.S.M.E. Members (Total personnel, 19)

John Haydock, *Chairman*
Earle Buckingham
T. H. Doan, Jr.
B. P. Graves
J. J. McBride
E. R. Smith

No. 7 on Twist Drill Sizes

A.S.M.E. Members (Total personnel, 6)

W. C. Mueller, *Chairman* †
J. H. Horigan

No. 8 on Jig Bushings

A.S.M.E. Member (Total personnel, 8)

J. H. Horigan

SUBGROUP CHAIRMEN

Subgroup on Liner Outer Diameters and Tolerances (to be appointed)

No. 9 on Punch Press Tools

A.S.M.E. Members (Total personnel, 15)

D. H. Chason
N. W. Dorman
E. W. Ernest
H. E. Harris †
D. M. Palmer

No. 10 on Forming Tools and Holders

A.S.M.E. Members (Total personnel, 10)

W. C. Mueller, *Chairman* †
L. D. Spence

No. 11 on Chucks and Chuck Jaws

A.S.M.E. Member (Total personnel, 10)

J. E. Lovely, *Chairman*

SUBGROUP CHAIRMEN

No. 1 on Master Chuck Jaws, J. E. Lovely
No. 2 on Adapters for Air Cylinders, J. E. Lovely

No. 12 on Cut and Ground Thread Taps

(Total personnel, 7)

No. 13 on Splines and Splined Shafts

A.S.M.E. Members (Total personnel, 15)

J. B. Armitage
R. E. W. Harrison
F. O. Hoagland
J. E. Lovely

No. 17 on Nomenclature for Small Tools and Machine Tool Elements

A.S.M.E. Members (Total personnel, 12)

O. W. Boston, *Chairman and Secretary*
F. S. Blackall, Jr.
F. H. Colvin †
H. E. Harris †
F. O. Hoagland

Ex-Officio Members

A. N. Goddard
W. C. Mueller †

No. 19 on Single-Point Cutting Tools

A.S.M.E. Members (Total personnel, 2)

F. H. Colvin, *Chairman* †
O. W. Boston, *Secretary*

No. 20 on Reamers

A.S.M.E. Members (Total personnel, 16)

F. H. Colvin
T. F. Githens
J. H. Horigan
H. E. Wells

SUBGROUP CHAIRMAN

No. 1 on Reamer Proposal, C. M. Pond

No. 21 on Tool-Life Tests for Single-Point Tools

A.S.M.E. Members (Total Personnel, 11)

O. W. Boston, *Chairman*
M. F. Judkins

GEARS (B6)

** Joint sponsorship with the American Gear Manufacturers Association. Sectional Committee organized June, 1921*

A.S.M.E. Members (Total personnel, 27)

Earle Buckingham, *Vice-Chairman* †
C. B. LePage, *Acting Secretary*
G. H. Acker
U. S. Eberhardt
L. H. Fry
C. B. Hamilton, Jr.
D. T. Hamilton
M. R. Hanna
O. A. Leutwiler †
G. L. Markland, Jr.
Carleton Reynell

SUBCOMMITTEE CHAIRMEN

Executive Committee (to be appointed)
No. 1 on Program (to be appointed)
No. 2 on Editing Reports (to be appointed)
No. 3 on Nomenclature, D. T. Hamilton
No. 4 on Tooth Form (Spur Gears), U. S. Eberhardt
No. 5 on Helical Gears, W. P. Schmitter
No. 6 on Worm Gears, T. R. Rideout
No. 7 on Bevel Gears, F. L. Knowles
No. 8 on Materials, C. B. Hamilton, Jr.
No. 9 on Inspection, J. P. Breuer
No. 10 on Horsepower Rating, Earle Buckingham

PIPE FLANGES AND FITTINGS (B16)

** Joint sponsorship with the Heating, Piping and Air Conditioning Contractors National Association, and the Manufacturers Standardization Society of the Valve and Fittings Industry. Sectional Committee organized October, 1921*

A.S.M.E. Members (Total personnel, 50)

C. P. Bliss, *Chairman* †
J. J. Harman, *Secretary*
A. L. Baker
L. W. Benoit †
A. L. Brown
Sabin Crocker
Ferdinand Fink
V. M. Frost
H. E. Haller
J. S. Hess
H. A. Hoffer †
E. L. Hopping
A. M. Houser
C. A. Kelting †
J. R. Kruse (John Blizard, *Alternate*)
M. B. MacNeille
F. H. Morehead
L. S. Morse
Ludwig Skog
J. R. Tanner †
J. H. Taylor
Rowland Tompkins
G. W. Watts
J. H. Williams

SUBCOMMITTEE CHAIRMEN

Executive Committee, C. P. Bliss
No. 1 on Cast Iron Flanges and Flanged Fittings, A. M. Houser
No. 2 on Screwed Fittings, F. H. Morehead
No. 3 on Steel Flanges and Flanged Fittings, C. P. Bliss
No. 4 on Materials and Stresses, A. M. Houser
No. 5 on Face to Face Dimensions of Ferrous Flanged Valves, J. R. Tanner

PIPE FLANGES AND FITTINGS (B16)

(Continued)

No. 6 on Malleable Iron or Steel Brass Seat Unions (to be appointed)
No. 7 on Rating of Pipe Fittings (to be appointed)
No. 8 on Marking of Pipe Fittings, F. H. MORELAND
No. 9 on Port Openings (to be appointed)

SHAFTING (B17)

** Sole sponsorship. Organized October, 1918*

A.S.M.E. Members (Total personnel, 13)

C. M. CHAPMAN, *Chairman* †
C. B. LEPAGE, *Secretary*
H. C. E MEYER
L. C. MORROW
J. M. SHIMER
G. N. VAN DERHOEF †
L. W. WILLIAMS †

BOLT, NUT, AND RIVET PROPORTIONS (B18)

** Joint sponsorship with the Society of Automotive Engineers. Sectional Committee organized March, 1922*

A.S.M.E. Members (Total personnel, 55)

W. C. STEWART, *Secretary*
H. E. ALDRICH
F. C. BILLINGS
B. G. BRAINE
G. S. CASE
T. G. CRAWFORD
H. P. FREAR
A. M. HOUSER †
HERMAN KOESTER
S. F. NEWMAN
R. J. WHELAN
E. M. WHITING
V. R. WILLOUGHBY
(J. J. MCBRIDE, *Alternate*)

SUBCOMMITTEE CHAIRMEN

No. 1 on Large and Small Rivets (to be appointed)
No. 2 on Wrench-Head Bolts and Nuts (to be appointed)
No. 3 on Slotted Head Proportions (to be appointed)
No. 4 on Track Bolts and Nuts (to be appointed)
No. 5 on Round Unslotted Head Bolts (Carriage Bolts) (to be appointed)
No. 6 on Plow Bolts (to be appointed)
No. 7 on Body Dimensions and Materials (to be appointed)
No. 8 on Nomenclature, G. S. CASE
No. 9 on Socket Head Cap and Set Screws, HERMAN KOESTER

PLAIN AND LOCK WASHERS (B27)

** Joint sponsorship with the Society of Automotive Engineers. Sectional Committee organized August, 1925*

A.S.M.E. Members (Total personnel, 39)

EUGENE CALDWELL
T. G. CRAWFORD
B. S. LEWIS †
C. H. LOUTREL
J. J. MCBRIDE
H. C. E. MEYER
W. C. MUELLER †
E. M. WHITING †

SUBCOMMITTEE CHAIRMEN

No. 1 on Plain Washers, W. L. BARTH
No. 2 on Spring Washers, E. COWLIN

TRANSMISSION CHAINS AND SPROCKETS (B29)

** Joint sponsorship with the Society of Automotive Engineers, and the American Gear Manufacturers Association. Sectional Committee organized September, 1917. Reorganized December, 1926*

A.S.M.E. Members (Total personnel 13)

W. J. BELCHER
C. B. JAHNKE †
JOSEPH JOY
L. V. LUDY †
D. B. PERRY
C. R. WEISS
G. A. YOUNG

SUBCOMMITTEE CHAIRMEN

No. 1 on Roller Chain Standardization (to be appointed)
No. 2 on Silent Chain Standardization, G. A. YOUNG

CODE FOR PRESSURE PIPING (B31)

** Sole sponsorship. Sectional Committee organized March, 1926. Reorganized December, 1937*

A.S.M.E. Members (Total personnel, 101)

E. B. RICKETTS, *Chairman*
R. E. BRYANT
C. S. COLE
H. C. COOPER
D. H. COREY
SABIN CROCKER
H. D. EDWARDS
E. R. FISH
CHARLES FITZGERALD
V. M. FROST
T. W. GREENE
H. E. HALLER
W. D. HALSEY
J. S. HAUG
H. A. HOFFER
G. G. HOLLINS
E. L. HOPPING
A. M. HOUSER †
ALFRED IDDLES †
D. S. JACOBUS
T. M. JASPER
C. A. KELTING
E. H. KRIEG
G. SINDING-LARSON
M. B. MACNEILLE
G. W. MARTIN
H. C. E. MEYER
J. W. MOORE
(J. D. CAPRON, *Alternate*)
F. H. MOREHEAD
(J. J. HARMAN, *Alternate*)
H. H. MORGAN
L. S. MORSE, SR.
R. M. NEE
E. W. NORRIS
C. W. OBERT
GEO. A. ORROK
A. L. PENNIMAN, JR.
C. S. ROBINSON †
J. H. ROMANN
D. B. ROSSHEIM
G. W. SAATHOFF
G. K. SAURWEIN
LUDWIG SKOG
H. S. SMITH
(H. H. MOSS, *Alternate*)
J. R. TANNER
J. H. TAYLOR
J. H. VANCE
H. L. WHITTEMORE
J. H. WILLIAMS
T. F. WOLFE

SUBCOMMITTEE CHAIRMEN

No. 1 on Plan, Scope, and Editing, SABIN CROCKER
No. 2 on Power Piping, ALFRED IDDLES
No. 4 on Gas and Air Piping, J. S. HAUG
No. 5 on Refrigeration Piping, A. B. STICKNEY
No. 6 on Oil Piping, A. D. SANDERSON
No. 7 on Piping Materials and Identification, F. H. MOREHEAD
No. 8 on Fabrication Details, LUDWIG SKOG
No. 9 on District Heating Piping, G. K. SAURWEIN

Special Committee to confer with Boiler Code Subcommittee on Material Specifications, the M.S.S., the A.S.T.M. and Sectional Committee B31 and Sectional Committee B16 to coordinate the several specifications relating to piping, valves and fittings

WIRE AND SHEET METAL GAGES (B32)

** Joint sponsorship with the Society of Automotive Engineers. Sectional Committee organized November, 1928. Reorganized November, 1939*

A.S.M.E. Members (Total personnel, 35)

A. P. COTTLE
E. W. ERNEST
J. F. HOWE †
F. G. WILSON †

SUBCOMMITTEE CHAIRMAN

Wire and Sheet Metal Gages, H. W. TENNEY

SCREW THREADS FOR HOSE COUPLINGS (B33)

** Sole sponsorship. Sectional Committee organized August, 1928*

A.S.M.E. Members (Total personnel, 28)

A. L. BROWN, *Secretary*
A. F. BREITENSTEIN †
J. J. CROTTY
W. L. CURTISS
W. E. DUNHAM †
J. J. HARMAN
(F. C. ERNST, *Alternate*)
A. M. HOUSER
H. C. E. MEYER
J. H. WILLIAMS

SUBCOMMITTEE CHAIRMEN

Special Subcommittee to Draft Recommended Specifications (to be appointed)
Subcommittee on Basic Thread Dimensions, D. R. MILLER

WROUGHT IRON AND WROUGHT STEEL PIPE AND TUBING (B36)

** Joint sponsorship with the American Society for Testing Materials. Sectional Committee organized April, 1928*

A.S.M.E. Members (Total personnel, 44)

H. H. MORGAN, *Chairman*
SABIN CROCKER, *Secretary*
J. S. ADELSON
H. E. ALDRICH
NEWELL HAMILTON
E. L. HOPPING
(A. B. MORGAN, *Alternate*)

WROUGHT IRON AND WROUGHT STEEL PIPE AND TUBING (B36)

(Continued)

A. M. Houser †
D. S. Jacobus †
(F. S. Clark, *Alternate*) †
J. J. Kanter
H. C. E. Meyer
F. H. Morehead
H. B. Oatley †
Ludwig Skoog †
J. R. Tanner
A. E. White

SUBCOMMITTEE CHAIRMEN

No. 1 on Plan, Scope, and Editing, H. H. Morgan
No. 2 on Pipe and Tubing for Low Temperature Service, J. J. Shuman
No. 3 on Pipe and Tubing for High Temperature Service, J. R. Tanner
No. 4 on Materials, F. H. Morehead

PRESSURE AND VACUUM GAGES (B40)

** Sole sponsorship. Sectional Committee organized July, 1930*

A.S.M.E. Members (Total personnel, 44)

M. D. Engle, *Chairman*
A. W. Lenderoth, *Secretary* †
E. J. Bryant
J. P. Cavanaugh †
Paul Diserens
C. H. Graesser
W. F. Jones
R. J. Kehl
J. C. McCune †
A. H. Morgan
H. B. Reynolds
W. C. Schoenfeldt

SUBCOMMITTEE CHAIRMEN

No. 1 on Plan and Scope, M. D. Engle
No. 2 on Definitions, C. F. Schwep
No. 3 on Gage Sizes and Mounting Dimensions, H. B. Reynolds
No. 4 on Accuracy and Test Methods, O. J. Hodge

STOCK SIZES, SHAPES AND LENGTHS FOR HOT AND COLD FINISHED IRON AND STEEL BARS (B41)

** Sole sponsorship Sectional Committee organized June, 1930*

A.S.M.E. Members (Total personnel, 25)

F. H. Dechant
E. W. Ernest
H. D. Tanner
L. W. Williams †
G. H. Woodroffe

SUBCOMMITTEE CHAIRMEN

No. 1 on Hot Rolled Steel, Henry Wysor
No. 2 on Cold Finished Steels, L. E. Creighton
No. 3 on Hot Rolled Iron (to be appointed)

SPECIFICATIONS FOR LEATHER BELTING (B42)

** Sole sponsorship. Sectional Committee organized February, 1931*

A.S.M.E. Members (Total personnel, 24)

H. T. Coates
R. W. Drake †
W. E. Emley
King Hathaway
P. G. Rhoads
G. A. Schieren

SUBCOMMITTEE CHAIRMEN

No. 1 on Standard Specifications (to be appointed)
No. 2 on Recommendations for Selection, Care and Installation, G. A. Schieren

MACHINE PINS (B43)

** Joint sponsorship with the Society of Automotive Engineers, Sectional Committee organized March, 1926*

A.S.M.E. Members (Total personnel, 13)

E. J. Bryant †
J. J. McBride
H. C. E. Meyer

SUBCOMMITTEES

No. 1 on Straight, Taper and Dowel Pins (to be appointed)
No. 2 on Split Pins (to be appointed)

CLASSIFICATION AND DESIGNATION OF SURFACE QUALITIES (B46)

** Joint sponsorship with the Society of Automotive Engineers. Sectional Committee organized May, 1932*

A.S.M.E. Members (Total personnel, 63)

E. J. Abbott
E. J. Bryant
T. G. Crawford
R. C. Deale †
U. S. Eberhardt
S. A. Einstein
R. F. Gagg
W. W. Gilbert
J. J. Harman
R. E. W. Harrison †
F. V. Hartman
F. O. Hoagland
H. J. Holtzclaw
R. T. Kent
H. F. Kurtz
F. C. Spencer
C. C. Stevens
W. C. Stewart
J. S. Tawresey
C. H. Whitaker
Ernest Wooler

SUBCOMMITTEE CHAIRMEN

Executive Committee (to be appointed)
No. 2 on Surfaces Produced by Molds, Dies, Rolls, or Any Other Means of Deforming Materials (to be appointed)
No. 3 on Coated Surfaces, G. B. Hogaboom
No. 4 on Symbols for Indicating Surface Quality on Drawings, T. G. Crawford
No. 5 on Ways, Means and Apparatus for Measuring Quality of Surface (to be appointed)
No. 7 on Standards for Appearance of Surfaces (to be appointed)

COMBUSTION SPACE FOR SOLID FUELS (B50)

** Sole sponsorship. Sectional Committee organized June, 1933*

A.S.M.E. Members (Total personnel, 21)

C. E. Bronson, *Chairman*
W. G. Christy
John Hunter
A. J. Johnson
V. G. Leach †
J. P. Magos
J. F. McIntire
F. L. Meyer
C. A. Reed
John Van Brunt †

SUBCOMMITTEE CHAIRMEN

No. 1 on Purpose and Scope, C. E. Bronson
No. 2 on Combustion and Design, B. M. Guthrie
No. 3 on Warm Air Furnaces, J. H. Manny
No. 4 on Steel Heating Boilers, W. B. Russell
No. 5. on Cast Iron Boilers, J. F. McIntire

SCHEME FOR IDENTIFICATION OF PIPING SYSTEMS (A13)

** Joint sponsorship with the National Safety Council. Sectional Committee organized June, 1922*

A.S.M.E. Members (Total personnel, 35)

E. E. Ashley
W. L. Bunker
Crosby Field
E. L. Hopping
H. L. Miner
H. S. Smith
Frank Thornton, Jr.
Frank Umbehocker †

SUBCOMMITTEE CHAIRMEN

Executive Committee, A. S. Hebble
Identification by Colors (to be appointed)
Classification, Crosby Field
Identification Markings Other Than Color (to be appointed)
Editing Subcommittee, A. S. Hebble

MINIMUM REQUIREMENTS FOR PLUMBING AND STANDARDIZATION OF PLUMBING EQUIPMENT (A40)

** Sole sponsorship. Sectional Committee organized August, 1928*

A.S.M.E. Members (Total personnel, 52)

C. B. LePage, *Acting Secretary*
J. F. Carney, *Alternate*
C. S. Cole
A. M. Houser
G. W. Martin
(A. H. Morgan, *Alternate*)
W. K. McAfee
Thorndike Saville †
W. R. Webster †

SUBCOMMITTEE CHAIRMEN

Research Committee on Plumbing (to be appointed)
No. 1 on Minimum Requirements for Plumbing, T. I. Coe
No. 2 on Staple Vitreous China Plumbing Fixtures, H. R. Van Sciver
No. 3 on Staple Porcelain (All Clay) Plumbing Equipment, H. R. Van Sciver
No. 4 on Enameled Sanitary Ware, A. H. Cline, Jr.
No. 5 on Traps, A. R. McGonegal
No. 6 on Brass Plumbing Products (to be appointed)
No. 7 on Brass Fittings for Flared Copper Tubes, F. L. Riggin
No. 8 on Cast Iron Soil Pipe and Fittings (to be appointed)

MINIMUM REQUIREMENTS FOR PLUMBING AND STANDARDIZATION OF PLUMBING EQUIPMENT (A40)

(Continued)

No. 9 on Gasoline, Oil and Grease Separators (to be appointed)
Joint Committee on Threaded Cast Iron Pipe, F. H. MOREHEAD
No. 11 on Soldered Fittings for Tubing, A. M. HOUSER
No. 12 on Minimum Air Gaps in Plumbing Systems, W. K. MCAFEE

ROLLED THREADS FOR SCREW SHELLS OF ELECTRIC SOCKETS AND LAMP BASES (C44)

** Joint sponsorship with the National Electrical Manufacturers Association. Sectional Committee organized March, 1929*

A.S.M.E. Members (Total personnel, 16)

E. J. BRYANT †
EARLE BUCKINGHAM †
A. B. MORGAN
E. S. SANDERSON †

LETTER SYMBOLS AND ABBREVIATIONS FOR SCIENCE AND ENGINEERING (Z10)

** Joint sponsorship with the American Association for the Advancement of Science, American Institute of Electrical Engineers, American Society of Civil Engineers, and the Society for the Promotion of Engineering Education. Sectional Committee organized January, 1926. Reorganized October, 1935*

A.S.M.E. Members (Total personnel, 43)

S. A. MOSS, *Vice-Chairman* †
K. H. CONDIT
R. J. S. PIGOTT †
(S. R. BEITLER, *Alternate*) †
FRANK THORNTON, JR.
E. P. WARNER

SUBCOMMITTEE CHAIRMEN

Executive Committee, H. M. TURNER
Steering Committee, H. M. TURNER
No. 1 on Letter Symbols and Signs for Mathematics, A. A. BENNETT
No. 2 on Symbols for Hydraulics, J. C. STEVENS
No. 3 on Symbols for Mechanics, R. E. PETERSON
No. 4 on Symbols for Structural Analysis, ALBERT HAERTLEIN
No. 5 on Symbols for Heat and Thermodynamics, S. A. Moss
No. 6 on Symbols for Photometry, E. C. CRITTENDEN
No. 7 on Aeronautical Symbols, G. W. LEWIS
No. 8 on Symbols for Electric and Magnetic Quantities (to be appointed)
No. 9 on Symbols for Radio, H. M. TURNER

POWER TEST CODES COMMITTEES

ARTICLE B6A, PAR. 27: The Standing Committee on Power Test Codes shall, under the direction of the Council, have supervision of all the activities of the Society in connection with the A.S.M.E. Power Test Codes, including the interpretation of such codes.

The first Standing Committee on Power Test Codes was organized in December, 1918, to revise and extend the Power Test Codes which had been formulated by various technical committees appointed to develop particular codes. This work began in 1884.

STANDING COMMITTEE

FRANCIS HODGKINSON, *Chairman* (1944)
A. G. CHRISTIE, *Vice-Chairman* (1946)

THE WOMAN'S AUXILIARY TO THE A.S.M.E.

The Woman's Auxiliary to the A.S.M.E. was organized on May 10, 1923, and its Constitution and By-Laws was approved by the Council of the A.S.M.E. on October 27, 1924. The objects of the Auxiliary are to render service to all that pertains to the interest of the profession of mechanical engineering; to cooperate with any committees of the A.S.M.E.; and to assist the sons and daughters of the members of the Society or worthy students of mechanical engineering in obtaining scholarships; and to promote any other objects consistent with the aims or objects of the A.S.M.E.

OFFICERS

President, Mrs. F. M. Gibson
First Vice-President, Mrs. E. C. M. Stahl
Second Vice-President, Mrs. C. M. Sames
Third Vice-President, Mrs. R. F. Gagg
Fourth Vice-President, Mrs. E. F. Zeiner
Fifth Vice-President, Mrs. S. F. Duncan
Recording Secretary, Mrs. P. E. Frank
Corresponding Secretary, Mrs. A. R. Cullimore
Treasurer, Mrs. A. H. Morgan

STANDING COMMITTEE CHAIRMEN

Student Loan, Mrs. R. F. Gagg
Membership, Mrs. G. E. Hagemann
Calvin W. Rice Scholarship, Mrs. J. A. Brooks
Custodian, Miss Burtie Haar

COUNCIL REPRESENTATIVES

A. G. Christie
Warren H. McBryde

OFFICERS OF LOCAL SECTIONS

Cleveland

Chairman, Mrs. T. F. Githens

Los Angeles

Chairman, Mrs. S. F. Duncan

Metropolitan

Chairman, Mrs. J. Noble Landis
First Vice-Chairman, Mrs. Calvin W. Rice
Second Vice-Chairman, Mrs. C. H. Young
Third Vice-Chairman, Mrs. Earl Smith
Recording Secretary, Mrs. C. F. Kayan
Corresponding Secretary, Miss Burtie Haar
Treasurer, Mrs. C. E. Gus

Philadelphia

Chairman, Mrs. E. F. Zeiner

AWARDS

The following paragraphs deal with the medals, awards, scholarships, and loan funds which come within the jurisdiction of the A.S.M.E. Other awards available to Student Members are listed in *Mechanical Engineering*, February, 1938, page 183. The Society also participates with other engineering societies in a number of joint awards. Further details concerning all the awards will be found in a series of articles beginning in the October, 1938, issue of *Mechanical Engineering*.

Honorary Membership, to which persons of acknowledged professional eminence are elected by unanimous vote of Council under the provisions of the By-Laws and Rules. A list of honorary members is given on page RI-42.

Life Membership, which may be conferred by the Council for distinguished service to the Society; or secured by a member by payment for an annuity in accordance with the provisions of the By-Laws.

A.S.M.E. Medal, established by the Society in 1920 to be presented, together with an engraved certificate, for distinguished service in engineering and science. May be awarded for general service in science having possible application in engineering.

Holley Medal, instituted and endowed in 1924 by George I. Rockwood, Past Vice-President of the Society, to be bestowed, together with an engraved certificate, for some great and unique act of genius of engineering nature that has accomplished a great and timely public benefit.

Worcester Reed Warner Medal, provision for which was made in the will of Worcester Reed Warner, Honorary Member of the Society, is a gold medal to be bestowed, together with an engraved certificate, on the author of the most worthy paper received, dealing with progressive ideas in mechanical engineering or efficiency in management.

Melville Medal, established in 1914 by the bequest of Rear-Admiral George W. Melville, Honorary Member and Past-President of the Society, to be presented, together with an engraved certificate, for an original paper or thesis of exceptional merit, presented to the Society for discussion and publication, to encourage excellence in papers. The medal may be presented annually.

Spirit of St. Louis Medal, established by an endowment fund created in 1929 by citizens of St. Louis, Mo., to be awarded for meritorious service in the advancement of aeronautics. This medal will be awarded at the discretion of the Council of the Society at approximately three-year periods upon the recommendation of its Board of Honors and Awards.

Spirit of St. Louis Junior Award, established in 1938 by an endowment fund created by the General Committee for the 1935 Aeronautic Meeting in St. Louis; a cash award of $50, made every three years, for the best paper on an aeronautic subject presented at any A.S.M.E. meeting during the three-year period either personally by the author (a Junior Member of the Society under thirty years of age) or by a Junior Member designated by him, and submitted to the Committee on Medals within a reasonable period (to be determined by the Committee) after its initial presentation.

Pi Tau Sigma Medal Award, established in 1938, endowed by Pi Tau Sigma, the national honorary mechanical engineering fraternity, to be presented annually, together with an engraved certificate, to the young mechanical engineer for outstanding achievement in his profession within the ten years after graduation from a regular four-year mechanical engineering course of a recognized American college or university. Any mechanical engineering graduate, not more than thirty-five years of age, whose achievement has been all or in part in any field including industrial, educational, political, research, civic, etc., is eligible.

Junior Award, annual cash award of $50, established in 1914, from a fund created by Henry Hess, Past Vice-President of the Society, to be presented, together with an engraved certificate, for the best paper or thesis submitted by a Junior Member.

Charles T. Main Award, annual cash award of $150, established in 1919 from a fund created by Charles T. Main, Past-President of the Society, to be awarded, together with an engraved certificate, to a Student Member of the Society, for the best paper within the general subject of the influence of the profession upon public life. The exact subject is assigned by the Board of Honors and Awards, subject to the approval of the Council, and is announced each year through the Honorary Chairman of the Student Branches.

Student Awards, two annual cash awards of $25 each, established in 1914, from a fund created by Henry Hess, Past Vice-President of the Society, to be presented, together with engraved certificates, for the best papers or theses submitted by Student Members. The awards for 1932 and subsequent years have been given, one for undergraduate and the other for postgraduate work.

SCHOLARSHIPS AND LOAN FUNDS

Max Toltz: Loan Fund of $15,000 established by Major Max Toltz, former member of the Council of the Society, the income to be used for assistance to Student Members.

John R. Freeman: Fund of $25,000 established in 1926 by John R. Freeman, Past-President of the Society, the income to be used for travel scholarships and research.

Woman's Auxiliary: Scholarship or Fellowship offered by the Woman's Auxiliary to the Society to assist sons and daughters of members or worthy students of mechanical engineering.

RECIPIENTS OF AWARDS

The names of the recipients of the different awards to date are given in the following lists, together with the dates of presentation, and the services or papers for which the awards were made. There were no awards for the years not listed.

A.S.M.E. Medal

1921 Hjalmar Gotfried Carlson, in recognition of the services rendered the Government because of his invention and part in the production of 20,000,000 Mark III drawn steel booster casings used principally as a component of 75-mm high explosive shells, but also used extensively in gas shells and bombs

1922 Frederick Arthur Halsey, for his paper describing the premium system of wage payments presented before the Society at the Providence Meeting in 1891, as the adoption of the methods there proposed has had a profound effect toward harmonizing the relations of worker and employer

1923 John Ripley Freeman, for his eminent service in engineering and manufacturing by his meritorious work in fire prevention and the preservation of property

1926 R. A. Millikan, in recognition of his contributions to science and engineering

1927 Wilfred Lewis, for his contributions to the design and construction of gear teeth

1928 Julian Kennedy, for his services and contributions to the iron and steel industry

1929 William LeRoy Emmet, for his contributions in the development of the steam turbine, electric propulsion of ships and other power-generating apparatus

1931 Albert Kingsbury, for his research and development work in the field of lubrication

1933 Ambrose Swasey, for his contributions to the advancement of the engineering profession and for his part in the development of the turret lathe and the astronomical telescope

1934 Willis H. Carrier, in recognition of his research and development work in air-conditioning

1935 Charles T. Main, for distinguished achievements in the textile and other industries, in engineering education, and for eminent service to the engineering profession

1936 Edward Bausch, for meritorious mechanical development in the field of optics

1937 Edward P. Bullard, for outstanding leadership in the development of station-type machine tools

1938 Stephen J. Pigott, for outstanding leadership in marine propulsion and construction

1939 James E. Gleason, for service to the cause of safer and better transportation

1940 Charles F. Kettering, for outstanding inventions and research

1941 Theodor von Kármán, for his brilliance as a teacher, his researches in elasticity and many fields of physics and mechanics, and his distinguished leadership in the fields of aerodynamics and aircraft design.

Holley Medal

1924 Hjalmar Gotfried Carlson, for his inventions and processes which made possible the timely production of drawn steel booster casings for artillery ammunition, thereby aiding victory in the World War (diploma in recognition of achievements presented in 1921)
1927 Elmer Ambrose Sperry, for achievements and inventions that have advanced the naval arts, including the gyroscope that has freed navigation from the dangers of the fluctuating magnetic compass
1929 Baron Chuzaburo Shiba, for his contributions to knowledge through fundamental research, including the field of aerodynamics, by the development of ultra-rapid kinematographic methods
1934 Irving Langmuir, for his contributions to science and engineering, including the development of gas-filled incandescent lamps, thoriated filament for thermionic emission, atomic hydrogen welding, phase control operation of the thyratron tube, and fundamental research in oil films
1936 Henry Ford, for revolutionary influence through invention and practice on transportation and on mass production methods in manufacturing
1937 Frederick G. Cottrell, for preeminent public service—the invention of electric precipitation—advancement of the science of gas liquefaction—gifts for engineering research
1938 Francis Hodgkinson, for meritorious services in the development of the steam turbine
1939 Carl E. Johansson, in recognition of his pioneer work in the development of basic measuring gages
1940 Edwin Howard Armstrong, for his leadership in the field of radio communication
1941 John C. Garand, for the invention and development of the semi-automatic rifle, which has been adopted by the U.S. Army as the U.S. Rifle, Caliber .30, M1, an outstanding contribution to our national defense.

Worcester Reed Warner Medal

1933 Dexter S. Kimball, for his contributions to efficiency in management as exemplified by his recently revised "Principles of Industrial Organization" and by his many articles, engineering society papers, and public addresses
1934 Ralph E. Flanders, for his contributions to a better understanding of the relationship of the engineer to economic problems and social trends as exemplified by the many papers which he has presented
1935 Stephen Timoshenko, for his contributions to the theory of the design of elastic structures and the treatment of dynamics of moving machinery
1936 Charles M. Allen, for his early and continued hydraulic laboratory work and for the permanent value of the papers on his development of methods of testing large hydraulic turbine installations
1937 Clarence F. Hirshfeld, for his research and contributions to the theory and practice of heat-power engineering as exemplified by books and papers
1938 Lawford H. Fry, for contributions relating to improved locomotive boiler design and utilization of better materials in railway equipment
1939 Rupen Eksergian, for influential papers of permanent value in A.S.M.E. Transactions
1940 William Benjamin Gregory, for distinguished work in hydraulic engineering, which has been the basis for many engineering papers
1941 Richard Vynne Southwell, for his many distinguished services to engineering and science through papers and publications in many fields, including aeronautics, theory of structures, elasticity, and hydrodynamics.

Melville Medal

1927 Leon P. Alford, "Laws of Manufacturing Management"
1929 Joseph W. Roe, "Principles of Jig and Fixture Practice"
1930 Herman Diederichs and William D. Pomeroy, "The Occurrence and Elimination of Surge or Oscillating Pressure in Discharge Lines From Reciprocating Pumps"
1931 Arthur E. Grunert, "Comparative Performance of a Pulverized-Coal-Fired Boiler Using Bin System and Unit System of Firing"
1932 Alexey J. Stepanoff, "Leakage Loss and Axial Thrust in Centrifugal Pumps"
1933 William E. Caldwell, "Characteristics of Large Hell Gate Direct-Fired Boiler Units"
1935 Oscar R. Wikander, "Draft-Gear Action in Long Trains"
1936 H. A. Stevens Howarth, "The Loading and Friction of Thrust and Journal Bearings With Perfect Lubrication"
1937 Alfred J. Büchi, "Supercharging of Internal-Combustion Engines With Blowers Driven by Exhaust-Gas Turbines"
1938 Alphonse I. Lipetz, "Air Resistance of Railroad Equipment"
1939 Lester M. Goldsmith, for his paper, "High-Pressure High-Temperature Turbine-Electric Steamship *J. W. Van Dyke*"
1940 Carl A. W. Brandt, for his paper, "The Locomotive Boiler"
1941 Roger V. Terry, for his paper "Development of the Automatic Adjustable-Blade-Type Propeller Turbine."

Spirit of Saint Louis Medal

1929 Daniel Guggenheim, founder of the Guggenheim Fund for the Promotion of Aeronautics
1932 Paul Litchfield, for his work in encouraging and sponsoring airship design and construction in this country
1935 Will Rogers, for his splendid, constructive, and unselfish work in the achievement of aviation, and the building up of public confidence in aviation through his articles in the press, over the radio, and from the speaker's platform
1938 James H. Doolittle, for meritorious service in the advancement of aeronautics
1941 John E. Younger, for notable contributions to the science of airplane design, particularly in the conception, analysis, and supervision of the development of the fundamental design principles, requirements, and criteria which first assured the success of the pressure-cabin type of high-altitude airplane.

Spirit of Saint Louis Junior Award

1941 Wilbur W. Reaser, for his paper, "Calculation of the Heat Loss from an Airplane Cabin."

Pi Tau Sigma Medal

1938 Wilfrid E. Johnson, for his development work in the field of refrigeration
1939 John I. Yellott, Jr., in recognition of significant achievements in steam-flow research and engineering education; also contributions on "Supersaturated Steam" and "Condensation of Flowing Steam in Diverging Nozzles"
1940 George A. Hawkins, for significant achievements in high-pressure steam research and engineering education
1941 R. Hosmer Norris, for outstanding achievement in mechanical engineering, particularly in the heat-transfer field.

Junior Award

1915 Ernest O. Hickstein, "Flow of Air Through Thin Plate Orifices"
1916 L. M. McMillan, "The Heat Insulating Properties of Commercial Steam-Pipe Coverings"
1919 E. D. Whalen, "Properties of Airplane Fabrics"
1921 S. Logan Kerr, "Moody Ejector Turbine"
1922 R. H. Heilman, "Heat Losses From Bare and Covered Wrought-Iron Pipe at Temperatures up to 800 Degrees Fahrenheit"
F. L. Kallam, "Preliminary Report on the Investigation of the Thermal Conductivity of Liquids"
1923 S. S. Sanford and Sabin Crocker, "The Elasticity of Pipe Bends"
1924 R. H. Heilman, "Heat Losses Through Insulating Material"
1925 Gilbert S. Schaller, "An Investigation of Seattle as a Location for a Synthetic Foundry Industry"
1927 William M. Frame, "Stresses Occurring in the Walls of an Elliptical Tank Subjected to Low Internal Pressure"
1928 M. D. Aisenstein, "A New Method of Separating the Hydraulic Losses in a Centrifugal Pump"
1929 Arthur M. Wahl, "Stresses in Heavy, Closely Coiled Helical Springs"
1930 Ed Sinclair Smith, "Quantity-Rate Fluid Meters"
1931 M. K. Drewry, "Radiant-Superheater Developments"
1932 Edmond M. Wagner, "Frictional Resistance of a Cylinder Rotating in a Viscous Fluid Within a Coaxial Cylinder"
1933 Townsend Tinker, "Surface Condenser Design and Operating Characteristics"
1934 John I. Yellott, Jr., "Supersaturated Steam"
1935 Stanley J. Mikina, "Effect of Skewing and Pole Spacing on Magnetic Noise in Electrical Machinery"

1936 HARWOOD F. MULLIKAN, JR., "Evaluation of Effective Radiant Heating Surface and Application of the Stefan-Boltzman Law to Heat Absorption in Boiler Furnaces"
1937 LESLIE J. HOOPER, "American Hydraulic-Laboratory Practice"
1938 ARTHUR C. STERN, "Separation and Emission of Cinders and Fly Ash"
1940 ROBERT E. NEWTON, for his paper, "A Photoelastic Study of Stresses in Rotary Disks"
1941 JOHN T. RETTALIATA, for his paper, "The Combustion Gas Turbine."

CHARLES T. MAIN AWARD

1925 CLEMENT R. BROWN, Catholic University of America. Subject: "The Influence of the Locomotive on the Unity of the United States"
1926 W. C. SAYLOR, Johns Hopkins University. Subject: "The Effect of the Cotton Gin Upon the History of the United States During Its First Seventy Years"
1927 No Award. Subject: "Scientific Management and Its Effect Upon the Industries"
1928 ROBERT M. MEYER, Newark College of Engineering. Subject: "Scientific Management and Its Effect Upon Manufacturing"
1929 No Award. Subject: "The Influence of Engineering on Farm Production"
1930 JULES PODNOSSOFF, Polytechnic Institute of Brooklyn. Subject: "The Value of the Safety Movement in the Industries"
1931 ROBERT E. KLISE, University of Michigan. Subject: "Interchangeability—Its Development and Significance in Industry"
1932 MARSHALL ANDERSON, University of Michigan. Subject: "Apprenticeship and Vocational Training"
1933 GEORGE D. WILKINSON, JR., Newark College of Engineering Subject: "Progress in the Prevention of Smoke and Atmospheric Pollution"
1934 PHILIP P. SELF, Colorado State College. Subject: "Air Conditioning—Its Practicability and Relation to Public Welfare"
1935 G. LOWELL WILLIAMS, Lafayette College. Subject: "Coordinated Transportation—An Economic Comparison of Railroad, Bus, Truck, Water, and Air Transportation for Long and Short Haul"
1936 No Award. Subject: "Development in the Generation and Distribution of Power and Their Effect Upon the Consumer"
1937 ALLAN P. STERN, Case School of Applied Science. Subject: "The Influence of the Introduction of Labor Saving Machinery Upon Employment in the United States"
1938 EDWARD W. CONNOLLY, University of Detroit. Subject: "Economic Limitations in Engineering Design, With Concrete Examples"
1939 JAMES R. BRIGHT, Lehigh University. Subject: "The Economics of Investment in New Manufacturing Equipment—With Concrete Cases"
1940 FRANK DE POULD, Case School of Applied Science. Subject: "What Has Been the Effect of Technological Advance on Employment?"
1941 JOHN J. BALUN, University of Detroit. Subject: "The Need and Possibilities of Participation by Engineers in Public Affairs."

STUDENT AWARD

1916 BOYNTON M. GREEN, Stanford University, "Bearing Lubrication"
HOWARD E. STEVENS, Rensselaer Polytechnic Institute, "An Investigation of the Dynamic Pressure on Submerged Flat Plates"
M. ADAM, Louisiana State University, "The Adaptability of the Internal Combustion Engine to Sugar Factories and Estates"
1917 H. R. HAMMOND and C. W. HOLMBERG, The Pennsylvania State College, "Study of Surface Resistance With Glass as the Transmission Medium"
1919 C. F. LEH and F. G. HAMPTON, Stanford University, "An Experimental Investigation of Steel Belting"
W. E. HELMICK, Stanford University, "An Experimental Investigation of Steel Belting"
1920 HOWARD G. ALLEN, Cornell University, "Wire Stitching Through Paper"
1921 KARL H. WHITE, University of Kansas, "Forces in Rotary Motors"
RICHARD H. MORRIS and ALBERT J. R. HOUSTON, University of California, "A Report Upon an Investigation of the Herschel Type of Improved Weir"
1923 CHARLES F. OLMSTEAD, University of Minnesota, "Oil Burning for Domestic Heating"
H. E. DOOLITTLE, University of California, "The Integrating Gate: A. Device for Gaging in Open Channels"
1924 GEORGE STUART CLARK, Stanford University, "Two Methods Used for the Determination of the Gasoline Content of Absorption Oils in Absorption Plants"
L. J. FRANKLIN and CHARLES H. SMITH, Stanford University, "The Effect of Inaccuracy of Spacing on the Strength of Gear Teeth"
1925 HARRY PEASE COX, JR., Rensselaer Polytechnic Institute, "A Study of the Effect of End Shape on the Towing Resistance of a Barge Model"
W. S. MONTGOMERY, JR., and E. RAY ENDERS, JR., Pennsylvania State College, "Some Attempts to Measure the Drawing Properties of Metals"
1926 R. E. PETERSON, University of Illinois, "An Investigation of Stress Concentration by Means of Plaster of Paris Specimens"
CECIL G. HEARD, University of Toronto, "Pressure Distribution Over U.S.A. 27 Aerofoil With Square Wing Tips—Model Tests"
1927 ALFRED H. MARSHALL, Princeton University, "Evaporative Cooling"
ROGER IRWIN EBY, University of Washington, "Measurement of the Angular Displacement of Flywheels"
1928 CLARENCE C. FRANCK, Johns Hopkins University, "Condition Curves and Reheat Factors for Steam Turbines"
1929 FRANK VERNON BISTROM, University of Washington, "An Investigation of a Rotary Pump"
WILLIAM WALLACE WHITE, University of Washington, "An Investigation of a Rotary Pump"
1930 GERARD EDEN CLAUSSEN, Polytechnic Institute of Brooklyn, "High-Temperature Oxidation of Steel"
HAROLD L. ADAMS and RICHARD L. STITH, University of Washington, "A Wind Tunnel for Undergraduate Laboratory Experiments"
1931 JULES PODNOSSOFF, Polytechnic Institute of Brooklyn, "Pressure and Energy Distribution in Multi-Stage Steam Turbines Operating Under Varying Conditions"
1932 H. E. FOSTER, JR., University of Tennessee, "Factors Affecting Spray Pond Design" (Undergraduate Award)
WILLIAM A. MASON, Stanford University, "An Experimental Investigation of the Flame Propagation in Internal-Combustion Engines" (Postgraduate Award)
1933 HUGO V. CORDIANO, Polytechnic Institute of Brooklyn, "Thermal Analysis of Lithium-Magnesium System of Alloys" (Undergraduate Award)
JAMES A. OSTRAND, JR., Princeton University, "Sudden Enlargement in the Open Channel" (Postgraduate Award)
1934 H. REYNOLDS HUDSON, Georgia School of Technology, "Dynamic Balance and Functional Utility Applied to Automotive Design" (Undergraduate Award)
1935 CHARLES P. BACHA, Rutgers University, "The Behavior of Metals Subjected to Combined Stress" (Postgraduate Award)
ROBERT W. BEAL, Oregon State College, "Do Lubricating Oils Wear Out?" (Undergraduate Award)
1936 LEON B. STINSON, Oklahoma Agricultural and Mechanical College, "Polymerized Motor Fuels; Their Economic Significance" (Undergraduate Award)
DEWITT D. BARLOW, JR., Princeton University, "The Critical Speeds of Lateral Vibrations of Shafts with Gyroscopic Effects" (Postgraduate Award)
1937 GINO J. MARINELLI, Rensselaer Polytechnic Institute, "Investigation of the Towing Resistance of a Model Submarine Hull" (Undergraduate Award)
1938 MARSHALL C. LONG, Princeton University, "An Investigation Into the Angular Characteristics of an Adjustable Blade Current Meter" (Postgraduate Award)
DONALD C. MCSORLEY, Michigan State College, "Humidity Insulation" (Undergraduate Award)

1939 DAVID T. JAMES, Michigan State College, "Bells—Concerning Their Tones" (Undergraduate Award)

1940 GEORGE W. SHEPHERD, JR., Princeton University, "An Automatic Mechanical Control for Synchronizing Prime Movers" (Postgraduate Award)
EDWARD D. ROWAN, Oregon State College, "Powder Metallurgy (Undergraduate Award)

1941 G. WALKER GILMER, III, University of Florida, "Center of Pressure Characteristics of a Marconi Yacht Sail" (Undergraduate Award).

FREEMAN TRAVEL SCHOLARSHIP

1927 HERBERT N. EATON
1928 BLAKE R. VAN LEER
1929 ROBERT T. KNAPP
1931 REGINALD WHITAKER
1932 G. ROSS LORD
1933, 1934 H. J. CASEY
1935, 1936 VICTOR L. STREETER

HONORARY MEMBERS

HONORARY MEMBERS IN PERPETUITY

Alexander Lyman Holley, Founder of the Society. Died 1882.
John Edson Sweet, Founder of the Society. Died 1916.
Henry Rossiter Worthington, Founder of the Society. Died 1880.

DECEASED HONORARY MEMBERS

	ELECTED	DIED
Leon Pratt Alford	1941	1942
Horatio Allen	1880	1889
Lorenzo Allievi	1937	1941
Sir William Arrol	1905	1913
Sir John Audley Frederick Aspinall	1911	1937
William Wallace Atterbury	1925	1935
Sir Benjamin Baker	1886	1907
Johann Bauschinger	1884	1893
Sir Henry Bessemer	1891	1898
Sir Frederick Joseph Bramwell	1884	1903
John Alfred Brashear	1908	1920
Gustave Canet	1900	1908
Andrew Carnegie	1907	1919
Daniel Kinnear Clark	1882	1896
Rudolph Julius Emmanuel Clausius	1882	1888
Hutchinson I. Cone	1936	1941
Sir John Goode	1889	1892
Peter Cooper	1882	1883
Charles de Fréminville	1919	1936

Anatole Mallet	1912	1919
Charles H. Manning	1913	1919
Rear-Admiral George Wallace Melville	1910	1912
The Honorable Sir Charles Algernon Parsons	1920	1931
Charles Talbot Porter	1890	1910
Auguste C. E. Rateau	1919	1930
Sir Edward J. Reed	1882	1906
Franz Reuleaux	1882	1905
Calvin Winsor Rice	1931	1934
Palmer C. Ricketts	1931	1934
Henri Adolphe-Eugene Schneider	1882	1898
Charles M. Schwab	1918	1939
C. William Siemans	1882	1883
Viscount Ei-ichi Shibusawa	1929	1931
Ambrose Swasey	1916	1937
Elihu Thomson	1930	1937
Henry Robinson Towne	1921	1924
Henri Tresca	1882	1885
William Cawthorne Unwin	1898	1933
Samuel Matthews Vauclain	1920	1940
Oskar von Miller	1912	1934
Francis A. Walker	1886	1897
Worcester Reed Warner	1925	1929
George Westinghouse	1897	1914
Sir William Henry White	1906	1913
Sir Alfred Fernandez Yarrow	1914	1932

LIVING HONORARY MEMBERS

	ELECTED
William Lamont Abbott	1940
Robert W. Angus	1940
Edmund Bruce Ball	1939
Mortimer Elwyn Cooley	1928
Alex Dow	1936
William Frederick Durand	1934
Arthur M. Greene, Jr.	1940
Herbert Clark Hoover	1925
Clarence Decatur Howe	1941
David Schenck Jacobus	1934
Masawo Kamo	1929
Dexter Simpson Kimball	1939
Albert Kingsbury	1940
Charles Thomas Main	1939
George A. Orrok	1936
Grande Ufficiale Ing. Pio Perrone	1920
Edwin Jay Prindle	1939
Rear Admiral Samuel Murray Robinson	1941
James A. Seymour	1940
Aurel Stodola	1941
William H. Tschappat	1938
Henry Hague Vaughan	1939
Right Honorable Lord Weir	1920
Major General Charles Macon Wesson	1941
Orville Wright	1918

PAST-PRESIDENTS

A list of past vice-presidents, managers, treasurers, and secretaries will be found in the 1930 Record and Index, pages 10-12. Dates in parentheses denote year of death.

Alexander Lyman Holley, *Chairman of the Preliminary Meeting for Organization of The American Society of Mechanical Engineers* (1882)

1880–1882 Robert Henry Thurston (1903)
1883 Erasmus Darwin Leavitt (1916)
1884 John Edson Sweet (1916)
1885 Josephus Flavius Holloway (1896)
1886 Coleman Sellers (1907)
1887 George H. Babcock (1893)
1888 Horace See (1909)
1889 Henry Robinson Towne (1924)
1890 Oberlin Smith (1926)
1891 Robert Woolston Hunt (1923)
1892 Charles Harding Loring (1907)
1893–1894 Eckley Brinton Coxe (1895)
1895 Edward F. C. Davis (1895)
1895 Charles Ethan Billings (1920)
1896 John Fritz (1913)
1897 Worcester Reed Warner (1929)
1898 Charles Wallace Hunt (1911)
1899 George Wallace Melville (1912)
1900 Charles Hill Morgan (1911)
1901 Samuel T. Wellman (1919)
1902 Edwin Reynolds (1909)
1903 James Mapes Dodge (1915)
1904 Ambrose Swasey (1937)
1905 John Ripley Freeman (1932)
1906 Frederick Winslow Taylor (1915)
1907 Frederick Remsen Hutton (1918)
1908 Minard Lafever Holman (1925)
1909 Jesse Merrick Smith (1927)
1910 George Westinghouse (1914)
1911 Edward Daniel Meier (1914)
1912 Alexander Crombie Humphreys (1927)
1913 William Freeman Myrick Goss (1928)
1914 James Hartness (1934)
1915 John Alfred Brashear (1920)
1916 David Schenck Jacobus
1917 Ira Nelson Hollis (1930)
1918 Charles Thomas Main
1919 Mortimer Elwyn Cooley
1920 Fred J. Miller (1939)
1921 Edwin S. Carman
1922 Dexter Simpson Kimball
1923 John Lyle Harrington
1924 Frederick Rollins Low (1936)
1925 William Frederick Durand
1926 William Lamont Abbott
1927 Charles M. Schwab (1939)
1928 Alex Dow
1929 Elmer Ambrose Sperry (1930)
1930 Charles Piez (1933)
1931 Roy V. Wright
1932 Conrad N. Lauer
1933 A. A. Potter
1934 Paul Doty (1938)
1935 Ralph E. Flanders
1936 William L. Batt
1937 James H. Herron
1938 Harvey N. Davis
1939 Alexander G. Christie
1940 Warren H. McBryde
1941 William A. Hanley

TREASURERS

Apr. 1880—Dec. 1881	Lycurgus B. Moore *
Dec. 1881—Nov. 1884	Charles W. Copeland (1895)
1894—1925	William H. Wiley (1925)
1925—1935	Erik Oberg
1935—date	William D. Ennis

SECRETARIES

Organization Meeting, 1880	Samuel S. Webber, Jr. (1921)
Acting Secretary, Apr.-Nov. 1880	Lycurgus B. Moore *
Nov. 1880—Mar. 1883	Thos. Whiteside Rae *
1883—1906	Frederick R. Hutton (1918)
1906—1934	Calvin W. Rice (1934)
1934—date	Clarence E. Davies

* Deceased. Year not known.

CONSTITUTION, BY-LAWS, AND RULES

Amended to June 16, 1941

Article C1, Name and Government

Sec. 1. The name of this Society is The American Society of Mechanical Engineers.

Sec. 2. The Society is a corporation, organized April 7, 1880, and chartered under the laws of the State of New York, December 24, 1881.* A supplemental charter** was issued on October 17, 1907, when the Society was consolidated with the Mechanical Engineers' Library Association.

The principal offices of the Society shall be in the City of New York.

Sec. 3. The Society shall be governed by this Constitution, the By-Laws, and the Rules.

Article B1, Government

Par. 1 Every question which shall come before a meeting of the Society or of the Council or of a committee, shall be decided by a majority of the votes cast, unless otherwise provided in the Constitution, the By-Laws and the Rules, or by the laws of the State of New York.

Par. 2 The Rules contained in "Robert's Rules of Order Revised" shall govern the Society in all cases to which they are applicable, when not inconsistent with the By-Laws or the Rules of this Society.

Article C2, Objects

Sec. 1. The objects of this Society are to promote the art and science of mechanical engineering and the allied arts and sciences; to encourage original research; to foster engineering education; to advance the standards of engineering; to promote the intercourse of engineers among themselves and with allied technologists; and severally and in cooperation with other engineering and technical societies to broaden the usefulness of the engineering profession.

Sec. 2. The Society may approve or adopt any report, standard, code, formula, or recommended practice, but shall forbid and oppose the use of its name, emblem, or initials in any commercial work or business, except to indicate conformity with its standards or recommended practices.

Article B2, Purposes

Par. 1 The objectives of the Society shall be accomplished by:

A Advancing the theory and practice of engineering and the allied arts and sciences by:

(*a*) Encouraging engineering research, tests, and other original work.

(*b*) Encouraging the preparation of original papers on engineering topics.

(*c*) Holding meetings for the presentation and discussion of original papers and participating in international engineering congresses.

(*d*) Publishing papers and reports and disseminating knowledge and experience of value to engineers.

(*e*) Developing and promulgating standards, codes, formulas, and recommended practices.

(*f*) Offering awards and other honors to encourage contributions to engineering; conferring awards and other honors in recognition of meritorious contributions to engineering.

(*g*) Furthering the purposes of the Engineering Societies Library, of which the Library of this Society forms a part.

(*h*) Encouraging intercourse among engineers for the mutual exchange of knowledge and experience.

B Enhancing the status of the engineer by:

(*a*) Maintaining high technical and cultural standards for entrance to the Society.

(*b*) Cooperating with educational institutions in the maintenance of high standards of engineering education.

(*c*) Requiring a high standard of ethical practice by members of the Society.

(*d*) Aiding in the adoption of a high standard of attainment for the granting of the legal right to practice professional engineering.

(*e*) Fostering among engineering students the study of philosophy and history, tradition and achievement, duties, and social functions of the engineering profession.

(*f*) Encouraging the personal and professional development of young engineers.

(*g*) Supporting activities looking to the increased employment of engineers and seeking new opportunities for engineering service.

C Increasing the usefulness of the organized engineering profession by:

(*a*) Cooperating with other engineering and technical societies.

(*b*) Encouraging a high standard of citizenship among engineers.

(*c*) Encouraging engineers to participate in public affairs.

(*d*) Cooperating with governmental agencies in engineering matters.

(*e*) Publicity for the engineering profession through the achievements of engineers.

Par. 2 The closest possible cooperation with universities and technical schools qualified and equipped to assist in the development and conduct of special research work is favored and is strongly urged.

Par. 3 Cooperative, not competitive, methods should be worked out with existing research laboratories and activities in other organizations. Such cooperation could take the form of publication of papers and groups of papers where a definite industry desires to bring to the attention of engineers for the development of the industry, any problem or special research, without commercial bias.

Par. 4 Each suggested research must be presented, on its individual merit, for approval by the Council, which will in turn refer the matter to the appropriate authority or committee.

Par. 5. Specific requests to the Council for solicitation of funds are to be accompanied with full details for proposed scope, method of solicitation, and budget.

Par. 6 No contributor is to be specially favored on account of any contribution for a research in which he is interested and a contribution can be received only on the basis of general benefit to the industry.

Article R2, Affiliated Organizations

Rule 1 The Council may approve the affiliation with the Society of any engineering society or legally organized group of engineers whose objects are in accord with the traditions, precedents, and objects of this Society.

Rule 2 The term "Affiliated with The American Society of Mechanical Engineers" shall be used by any society or by individual members of it only while the respective governing boards of both societies continue the affiliation.

*The original charter or certificate of incorporation was reproduced in facsimile form in the Transactions for 1937, pages RI-37–RI-42.

**The Supplemental Charter of October 17, 1907, also provided that the number of Directors shall be twenty-two (22).

RULE 3 Affiliation with this Society of any other organization shall in no wise be interpreted as interfering with the independence, autonomy, and self-control of that organization under its own constitution or by-laws.

RULE 4 The Society shall not be responsible for any act of any affiliated society.

RULE 5 Affiliation with this Society of any other organization may be terminated by the governing board of either giving sixty (60) days' written notice to the governing board of the other.

ARTICLE C3, MEMBERSHIP

Sec. 1. The corporate membership shall consist of Fellows, Members, and Junior Members. In addition there shall be Honorary Members, Associates, and Student-members.

Sec. 2. The rights and privileges of every member shall be personal to himself and shall not be transferable except that each corporate member shall be entitled to vote on any question before the Society either in person or by a proxy given to a corporate member.

Sec. 3. Every person admitted to membership shall be subject to the Constitution of the Society, and to any amendments that may be made from time to time.

ARTICLE B3, MEMBERSHIP

PAR. 1 The Council shall have power by resolution from time to time, to fix the number of Honorary Members.

PAR. 2 A proxy may be given to a member entitled to vote, but shall not be valid for more than six (6) months. Such proxy shall be signed, with an attesting witness, by the member giving it and shall be submitted to the Secretary for verification of the right of the member to vote at the meeting at which the proxy is to be used.

PAR. 3 Proffered resignations shall be presented to the Council for action, and shall be accepted if the requirements have been met. Each resignation presented to the Council after the fiscal year has commenced (October first) must be accompanied by a statement from the Secretary that the member has paid his dues up to and including the expired portion of the current fiscal year, unless such resignation is presented by January first, when no payment of current dues shall be required.

ARTICLE R3, MEMBERSHIP

RULE 1 Each member shall be entitled to a certificate of membership, signed by the President and the Secretary of the Society; it shall remain the property of the Society and be returned on demand. Each member requesting a certificate shall pay the cost of engrossing.

Rule 2 Abbreviations of the titles to be used by members are as follows:

Honorary Member	Hon. Mem. A.S.M.E.
Fellow	Fellow A.S.M.E.
Member	Mem. A.S.M.E.
Associate	Assoc. A.S.M.E.
Junior Member	Jun. A.S.M.E.
Student-member	Student A.S.M.E.

RULE 3 Each member shall be entitled to wear the emblem approved by the Council for his grade of membership.

RULE 4 Each member desiring to resign shall deposit with the Secretary any badge and certificate of membership in his possession, and upon acceptance of his resignation the Secretary shall make him the stipulated refund for his badge.

ARTICLE C4, QUALIFICATIONS FOR ADMISSION

Sec. 1. Members of all grades shall be elected by the Council.

Sec. 2. An Honorary Member shall be a person of acknowledged professional eminence.

Sec. 3. A Fellow shall be an engineer who shall have distinct engineering attainments, twenty-five (25) years of active practice in the profession of engineering or teaching of engineering in a school of accepted standing, and shall have been thirteen (13) years in the grade of Member. Graduation from an engineering school of accepted standing shall be considered equivalent to four (4) years of active practice.

Sec. 4. An engineer lacking the qualifications of Section 3 who has distinguished engineering or scientific attainments may be elected a Fellow by unanimous vote of Council members voting.

Sec. 5. A Member shall be an engineer or teacher of engineering who shall have reached the age of thirty (30) years and who shall have had nine (9) years active practice in the profession of engineering or teaching, three (3) years of which shall have been in a position of responsible charge of important work and who is qualified to design as well as direct such work. Graduation from a school of engineering of accepted standing shall be considered equivalent to four (4) years of active practice.

Sec. 6. An Associate need not be an engineer but must have a record of recognized leadership in some profession, or branch of industry, or science relating to engineering, and shall be qualified to cooperate with engineers in the practice of their profession and he must be at least thirty (30) years of age.

Sec. 7. A Junior Member shall be a graduate of a school of engineering of accepted standing or one who has equivalent attainments.

Sec. 8. A Student-member shall be a student regularly enrolled and pursuing an approved engineering curriculum in a school having a Student Branch of this Society.

ARTICLE B4, QUALIFICATIONS FOR ADMISSION

PAR. 1 A candidate for admission to the Society in any grade, except Honorary Membership, or a member desiring to change his grade, shall make application to the Council on an approved form.

PAR. 2 Fifteen (15) affirmative votes of the Council shall be required for the election of a candidate for any grade except Honorary Membership. Two (2) negative votes shall defeat an election.

PAR. 3 Each approved candidate shall be assigned by the Council to the grade of membership to which, in its judgment, his qualifications entitle him.

PAR. 4 Nomination for Honorary Membership may be made to the Council by at least twenty-five (25) members of the Society, who shall in all cases state in writing the grounds upon which the nomination is made.

PAR. 5 Election to Honorary Membership shall be by letter-ballot of the Council. Ballots shall be mailed by the Secretary to each member of the Council at least twenty-one (21) days in advance of the date set for the closure of such election. One (1) negative vote shall defeat an election to Honorary Membership.

PAR. 6 All matters relating to admissions to and promotions in membership shall be in charge of the Standing Committee on Admissions, under the direction of the Council.

PAR. 7 A Student-member may participate in all the activities of the Society but shall not be permitted to vote or hold an elective office except in the Student Branch located at the college of which he is a student.

PAR. 8 A Student-member shall not remain in this grade beyond the end of the Society's fiscal year in which he terminates his enrollment as a student.

ARTICLE R4, QUALIFICATIONS FOR ADMISSION

RULE 1 A candidate for admission to the Society as a Fellow, a Member, or an Associate, should refer to at least five (5) members who have personal knowledge of his qualifications and the grade of reference shall be as follows:

For Fellow, at least one (1) Fellow and the remainder Members
For Member, at least five (5) Fellows or Members

For Associate, at least three (3) Fellows or Members and the remainder Associates.

RULE 2 A candidate for admission to the Society as a Junior Member should refer to at least three (3) members who have personal knowledge of his qualifications, at least one of whom shall be a Fellow, Member, or Associate.

RULE 3 A candidate for admission to the Society as a Student-member must be endorsed by the Honorary Chairman in office at the Student Branch located at the college where he is a student.

RULE 4 An application for membership from a candidate who may not be able to give the necessary number of references may be recommended to the Council for ballot after sufficient evidence has been secured to show that the candidate is worthy of admission to membership. Such candidates may refer to officers or voting members of other societies of like standing.

RULE 5 An application may be referred by the Committee on Admissions to the executive committee of the Local Section to which the applicant would be logically attached, for information and comment by such local committee. If, after a period of twenty (20) days, no comment is received from the local committee, the Committee on Admissions will proceed with the consideration of the application.

RULE 6 The references for each candidate shall be requested to make such confidential communications to the Committee on Admissions as will enable it to arrive at a proper estimate of the eligibility of the candidate.

RULE 7 The Committee on Admissions shall report to each session of the Council the names of all candidates together with the recommendation on each. The Committee on Admissions shall meet monthly to receive and scrutinize applications, and shall seek further information as to the qualification of a candidate whose evidence of eligibility is not clear to them.

RULE 8 All confidential correspondence in relation to each candidate shall be destroyed by the administrative officer in charge of membership admissions within a reasonable period after acceptance of election by payment of the initiation or promotion fees and dues.

RULE 9 The Secretary shall mail to each member of the Council a ballot of the names and respective grades of the candidates for membership approved by the Committee on Admissions after having been duly posted in the publications of the Society. The voter shall prepare his ballot by crossing out the name of any candidate rejected by him, and shall enclose the ballot in an envelope and seal it. He shall enclose this envelope in a second envelope and sign it for identification. A ballot without the autographic endorsement of the voter on the outer envelope is defective and shall be rejected.

RULE 10 The Secretary shall count the ballots cast by the Council for election of new members, notify the applicants of their election, and regularly report the results of the ballot at the Council meeting next following each election. The names of applicants who are not elected shall neither be announced nor recorded.

ARTICLE C5, FEES AND DUES

Sec. 1. Initiation Fees:

Honorary Member	None
Fellow	$30
Member	25
Associate	25
Junior Member	10
Student-Member	None
Promotion Fees:	
From Member to Fellow	5
From Junior Member to Member or Associate (Except that an applicant under the age of 33 who has been a Junior Member in good standing for five consecutive years may be promoted without fee.)	10
From Student-member to Junior Member	None

Sec. 2. The annual dues for membership in each grade shall be:

Fellow	$25
Member	20
Associate	20
Junior Member until reaching the age of 30	10
Junior Member between the ages of 30 and 33	$15
Junior Member after reaching the age of 33	20
Student-member	as provided in the By-Laws

Sec. 3. The Council may permit any Fellow, Member, or Associate to become a life member in the same grade.

Sec. 4. The Council may remit the dues of any member for any special reason.

ARTICLE B5, FEES AND DUES

PAR. 1 The initiation fee and that part of the annual dues from the first month following the date of election to the first day of October, shall be due and payable on the first day of the month following the date of election. Only upon the payment of this amount shall the person elected be entitled to the rights and privileges of membership in the grade to which he is assigned. If such person does not comply with this requirement within three (3) months after notice of his election, the Council may declare his election void.

PAR. 2 The annual dues for each ensuing year shall be due and payable in advance on the first day of October.

PAR. 3 A bill for annual dues shall be mailed to each member by October first of each year. Notice of arrears shall be sent thereafter, as directed by the Council.

PAR. 4 At its first meeting in the calendar year the Secretary shall submit to the Council a list of members whose dues have remained unpaid for three (3) months. The Council may order the withholding of the publications for such delinquents.

PAR. 5 At its first meeting after the close of the fiscal year on September thirtieth, the Secretary shall submit to the Council a list of members whose dues have remained unpaid for twelve (12) months. Such delinquents shall, in the discretion of the Council, be stricken from the roll of membership and shall cease to have any further rights as members.

PAR. 6 If, in the case of non-payment of dues, the right to receive the publications of the Society or to vote be questioned, the books of the Society shall be conclusive evidence.

PAR. 7 The Council may temporarily excuse from payment of annual dues any member who from ill health, advanced age or good reason assigned is unable to pay such dues; and the Council may remit the whole or part of dues in arrears, or accept in lieu thereof desirable additions to the Library, or collections.

PAR. 8 The Council may restore to membership any person dropped from the rolls for non-payment of dues or otherwise, upon such conditions as it may deem best.

PAR. 9 The annual dues for a Student-member shall be $3.00 for the fiscal year beginning October first. Eight issues of *Mechanical Engineering*, October to May inclusive, shall be included in the dues for a Student-member.

PAR. 10 For distinguished service to the Society, the Council may confer life membership upon any Fellow or Member. Proposal for such action must be made at a regular meeting of the Council. Immediately following that meeting, the Secretary shall send to the members of the Council a letter ballot upon the proposal, this ballot to close in sixty (60) days. Fifteen (15) affirmative votes shall be required to approve and one (1) dissenting vote shall disapprove such proposal.

PAR. 11 A Fellow, Member, or Associate may become a Life Fellow, Life Member, or Life Associate by paying the Society at one time the present worth of an annuity equal to that member's dues for the period for which he is required to pay dues.

PAR. 12 The Council shall confer life membership upon any Fellow, Member, or Associate of the Society who has paid dues for thirty-five (35) years, or who shall have reached the age of seventy (70) years after having paid dues for thirty (30) years (Student-membership years not included).

Article R5, Fees and Dues

Rule 1 A Student-member recommended by the Honorary Chairman of his Student Branch may be elected by the Council to Junior membership, the election being subject to his graduation. The payment of dues as a Junior Member for one year at any time prior to September 30 of the calendar year following the calendar year in which he graduates, shall constitute acceptance of election and shall give him all the rights and privileges of the Junior Member grade from the date of such payment to September 30 of the calendar year following the calendar year in which he graduated.

Rule 2 The Student-member may pay an initial quarter year's dues, $2.50, to indicate acceptance of election. If he chooses this method, the remaining three quarter's of the dues, $7.50, shall be due not later than the first of the month following a three months' period thereafter. If he follows this procedure he will receive publications for the periods paid but no other services until election is accepted by payment of the full year's dues. If he does not accept or follow this procedure and complete his payments before September 30 of the calendar year following the calendar year in which he graduated, the automatic scheme of transfer without initiation fee expires and thereafter he must make a new application for Junior membership and if elected pay an initiation fee of $10.00.

Article C6, The Council (Directors)

Sec. 1. The affairs of the Society shall be managed by a Board of Directors, chosen from its membership and styled "The Council" which shall have full control of the activities of the Society, subject to the limitations of the Constitution and the results of letter ballots (Article B9, Par. 4 and Article B6, Par. 3).

Sec. 2. The Directors of the Society shall consist of a President, seven (7) Vice-Presidents, nine (9) Managers, and the last five (5) surviving Past-Presidents.

Sec. 3. The Directors may at any time, whenever sufficient cause shall appear to them, delegate to any corporate member of the Society the performance of any duties required by the Constitution to be performed by any Director.

Sec. 4. The Council shall meet immediately after the close of the Annual Meeting of the Society, at such other times as the Council may select, and at the call of the President. Eight members shall constitute a quorum of the Council.

Sec. 5. The Council shall present at the Annual Meeting of the Society a report verified by the President and the Treasurer or by twelve (12) members of the Council, showing the whole amount of real and personal property owned by the Society, where located, and where and how invested, and the amount and nature of the property acquired during the year immediately preceding the date of the report, and the manner of the acquisition; the amount applied, appropriated, or expended during the year immediately preceding such date, and the purpose, object, or persons to or for which such applications, appropriations, or expenditures have been made; also a report verified by the Secretary, giving the names and places of residence of the persons who have been admitted into membership in the Society during the year.

These reports shall be filed with the records of the Society, and an abstract shall be entered in the minutes of the proceedings of the Annual Meeting of the Society.

Article B6, The Council

Par. 1 The Council shall consider the failure of any incumbent, from inability or otherwise, to perform the duties of his office, and may, by a two-thirds vote, decree any elective office vacant. The Council shall thereupon appoint a member to fill the vacancy until the next election of officers, except for the office of the President, which shall be filled by the Vice-President serving his second year, who is senior by length of membership in the Society. Such appointment shall not render the appointee ineligible for election to any office.

Par. 2 An act of the Council which shall have received the expressed or implied sanction of the membership at the following meeting of the Society, shall be deemed to be an act of the Society and cannot afterward be impeached by any member.

Par. 3 The Council shall order the submission to the membership for decision by letter-ballot of any question of major importance involving a departure from usual custom. The Council shall appoint tellers to canvass such a ballot, the result of which shall be binding.

Article B6A, Standing and Special Committees

Par. 1 The Council shall at its first meeting of each year appoint from among its members an Executive Committee. Such committee shall consist of the President, two Vice-Presidents, and two Managers, with voting power; also the Chairman of the Finance Committee, the Chairman of the Committee on Professional Divisions and the Chairman of the Local Sections Committee, without voting power. During the intervals between sessions of the Council, the Executive Committee shall have and exercise all the general powers of the Council, except the power to fill vacancies in the Council, or to amend the By-Laws. The committee shall meet at the call of the President. The Secretary may take part in the deliberations of the Executive Committee, without vote. The Executive Committee shall keep minutes of its proceedings which shall be promptly reported to each member of the Council for approval.

Par. 2 Upon the recommendation of a business meeting of the Society or upon its own initiative, the Council shall have the power to appoint, as it may deem desirable, an Administrative Committee to assist in the conduct of the affairs of the Society. Any proposed expenditure of such a committee must be authorized by the Council before it is incurred.

Par. 3 Upon the recommendation of a business meeting of the Society or upon its own initiative, the Council shall have the power to appoint, as it may deem desirable, any Professional Committee to investigate and report upon a subject of engineering interest, except that the procedure of the American Standards Association shall be followed in organizing Sectional Committees. (See Paragraphs 10 and 11 of Article B6B.) Any proposed expenditure of such a committee must be authorized by the Council before it is incurred.

Par. 4 Administrative and Professional Committees shall be standing or special, as the By-Laws and Rules provide and the Council approves. The Chairmen of Standing Committees shall be entitled to a seat in the Council, but no vote. The term of office of one (1) member of each Standing Committee shall expire at the close of each Annual Meeting.

Par. 5 Each committee shall perform the duties required by the By-Laws and Rules, or assigned to it by the Council.

Par. 6 The Council may terminate membership on any committee on account of continued absence of the member, from inability or otherwise.

Par. 7 The President shall appoint a member to fill each vacancy in the Standing Committees.

Par. 8 Each committee shall at its first meeting elect a Chairman to serve for one (1) year.

Par. 9 A member of a Standing Committee whose term of office has expired, shall continue to serve until his successor has been elected or appointed.

Par. 10 On or before the fifteenth day of October of each year, each Standing Committee shall deliver to the Secretary a written report of its work for presentation to the Council. The Council may embody such report in its Annual Report.

Par. 11 On or before the fifteenth day of October of each year, each Special Committee shall deliver a written progress report to the Secretary for presentation to the Council. Upon receipt of this report, the Council may, in its discretion, continue the committee.

The committee shall be discharged upon the adoption of the final report.

PAR. 12 The Standing Committee on Finance shall, under the direction of the Council, have supervision of the financial affairs of the Society, including the books of account. The Committee shall consist of five (5) members of the Society, the term of one (1) member expiring at the close of each Annual Meeting, and two (2) members of the Council, the term of one (1) member expiring at the close of each Annual Meeting.

PAR. 13 The Standing Committee on Meetings and Program shall, under the direction of the Council, have supervision of the Meetings of the Society, except business meetings. The Committee shall consist of five (5) members, and the term of one (1) member shall expire at the close of each Annual Meeting.

PAR. 14 The Standing Committee on Publications shall, under the direction of the Council, have supervision of the publications of the Society. The Committee shall consist of five (5) members and the term of one (1) member shall expire at the close of each Annual Meeting.

PAR. 15 The Standing Committee on Admissions shall determine the eligibility of applicants for membership, and for transfer in membership grades, and shall make recommendation to the Council on each. The Committee shall consist of five (5) members and the term of one (1) member shall expire at the close of each Annual Meeting.

PAR. 16 The Standing Committee on Professional Divisions shall, under the direction of the Council, have supervision of the Professional Divisions of the Society. The Committee shall consist of five (5) members and the term of one (1) member shall expire at the close of each Annual Meeting.

PAR. 17 The Standing Committee on Local Sections shall, under the direction of the Council, have supervision of the Local Sections of the Society. The Committee shall consist of five (5) members and the term of one (1) member shall expire at the close of each Annual Meeting.

PAR. 18 The Standing Committee on Constitution and By-Laws shall, under the direction of the Council, have supervision of matters affecting the Constitution, By-Laws, and Rules, and shall report on all matters in this connection referred to it by the Council. The Committee shall consist of five (5) members and the term of one (1) member shall expire at the close of each Annual Meeting.

PAR. 19 The Standing Committee, designated as the Board of Honors and Awards shall, under the direction of the Council, have supervision of the awards of the Society as detailed in the Rules or prescribed by the Council. Recommendations for representatives of joint bodies of award shall be made to the Council by this Board. The Board shall consist of five (5) members and the term of one (1) member shall expire at the close of each Annual Meeting.

PAR. 20 The Standing Committee on Relations With Colleges shall, under the direction of the Council, have supervision of the Student Branches of the Society and of such work of the Society as aims to further the education of engineers through the colleges and schools of accepted standing. The Committee shall consist of five (5) members and the term of one (1) member shall expire at the close of each Annual Meeting.

PAR. 21 The Standing Committee on Education and Training for the Industries shall, under the direction of the Council, have supervision of such work of the Society as deals with education and training for the industries through agencies other than the colleges and engineering schools. The Committee shall consist of five (5) members and the term of one (1) member shall expire at the close of each Annual Meeting.

PAR. 22 There shall be a Standing Committee on Library, which shall represent the Society on the Library Board of the United Engineering Trustees, Inc. The number of members of this Committee and their terms of office shall be as required by the by-laws of the United Engineering Trustees, Inc.

PAR. 23 The Standing Committee on Standardization shall advise the Council on the dimensional standardization work of the Society, including relations with the American Standards Association. The Committee shall consist of five (5) members and the term of one (1) member shall expire at the close of each Annual Meeting.

PAR. 24 The Standing Committee on Research shall, under the direction of the Council, have supervision of the research activities of the Society. The Committee shall consist of five (5) members and the term of one (1) member shall expire at the close of each Annual Meeting.

PAR. 25 The Standing Committee on Safety shall advise the Council on the activities of the Society having to do with engineering and industrial safety, except the activities of the Boiler Code Committee, for which special provision is made. This Committee shall consist of five (5) members and the term of one (1) member shall expire at the close of each Annual Meeting.

PAR. 26 The Special Committee on Boiler Code shall, under the direction of the Council, have supervision of all activities of the Society in connection with the A.S.M.E. Codes for Pressure Vessels, including the interpretations of these codes. The Committee shall be appointed by the President and confirmed by the Council, and the President shall fill all vacancies in the Committee.

PAR. 27 The Standing Committee on Power Test Codes shall, under the direction of the Council, have supervision of all the activities of the Society in connection with the A.S.M.E. Power Test Codes, including the interpretation of such codes. The Committee shall consist of twenty-five (25) members and the terms of five (5) members shall expire at the close of each Annual Meeting.

PAR. 28 The Standing Committee on Professional Conduct shall, under the direction of the Council, have supervision of all matters relating to the Code of Ethics and its enforcement. The Committee shall consist of five (5) members and the term of one (1) member shall expire at the close of each Annual Meeting.

B6B, SOCIETY REPRESENTATION

PAR. 1 The Council may, in its discretion, appoint a member or members, or other person or persons, to represent it at meetings of societies of kindred aim or at public functions. Such delegates shall be designated as "Honorary Vice-Presidents," and their duties shall terminate with the occasion for which they are appointed.

PAR. 2 The President, subject to the approval of the Council, may nominate or appoint a member or members, or other person or persons, to represent the Society on professional or other committees organized by other societies or by Government departments or bureaus, or otherwise.

PAR. 3 The Council shall elect three (3) Trustees to serve on the Board of Trustees of the United Engineering Trustees, Inc., as required in the by-laws of that body.

PAR. 4 The Council shall appoint delegates to serve on the American Engineering Council as required in the by-laws of that body. If the number of delegates required to serve is at variance with the number elected or in office, the Council of the Society is empowered to make adjustments necessary. The President of the Society in office shall be the Chairman of the delegation of this Society to the meetings of the American Engineering Council, and the Chairman of the A.S.M.E. representatives on the Executive Board.

PAR. 5 The Council shall designate the Standing Committee on Library to serve as the Society's representatives on the Library Board of the United Engineering Trustees, Inc., as required in the by-laws of that body.

PAR. 6 The Council shall nominate to the United Engineering Trustees, Inc., two (2) members of the Society to serve on the Engineering Foundation as required in the by-laws of that body

PAR. 7 The Council shall appoint such number of members to represent the Society on the following agencies as may be required by the by-laws of those bodies, namely: John Fritz Medal Board of Award, Washington Award Commission of the Western Society of Engineers, Gantt Medal Board of Award, Daniel Guggenheim Medal Fund, Inc., Hoover Medal Board of Award, Alfred Noble Prize.

PAR. 8 The Council shall nominate three (3) members to represent the Society on the Division of Engineering of the

National Research Council as required in the by-laws of that body.

PAR. 9 The Council shall appoint three (3) members of the Society to represent the Society on the Engineers' Council for Professional Development.

PAR. 10 The Council shall designate such number of members to represent the Society on the American Standards Association as may be required by the constitution of that body.

PAR. 11 The representatives of the Society on Sectional Committees, organized under the rules of the American Standards Association, shall be appointed by the President, subject to the approval of the Council.

ARTICLE C7, ELECTION OF DIRECTORS

Sec. 1. The membership of the Society shall elect annually a Regular Nominating Committee, whose duty shall be to select candidates for the executive offices to be filled at each annual election.

Sec. 2. Other nominating committees having the same powers may be constituted by the membership of the Society.

Sec. 3. Directors shall be elected annually by sealed letter-ballot of the membership.

Sec. 4. The President shall be elected for one (1) year, the Vice-Presidents for two (2) years, the Managers for three (3) years. The Council shall have power to fill vacancies in its membership by appointment until the next election, except that the office of president shall be filled by the vice-president who is senior by length of membership in the Society.

ARTICLE B7, ELECTION OF DIRECTORS

PAR. 1 The Regular Nominating Committee of the Society shall consist of eight (8) members with eight (8) alternates elected at the Annual Meeting. The Chairman of the outgoing Nominating Committee shall serve as an advisory member, without vote, and the Secretary of the outgoing Committee may serve as alternate for him.

PAR. 2 The members and alternates of the Regular Nominating Committee shall be elected for one (1) year, and no member or alternate shall be eligible for more than two (2) consecutive terms. Serving as an alternate shall not affect the eligibility of a member to serve on the committee for two (2) terms.

PAR. 3 For the purpose of nominating members of the Regular Nominating Committee, the Council shall, on or before the first day of October of each year, associate the Local Sections into eight (8) groups, each group to be responsible for nominating one (1) member of the Committee. The Sections which will comprise these groups shall, as far as possible, be contiguous geographically to each other.

PAR. 4 The names of those elected to serve on the Regular Nominating Committee shall be published by the Secretary by the first week in February of each year, accompanied by a request for suggestions for nominees.

PAR. 5 A vacancy in a Regular Nominating Committee of the Society shall be filled by the alternate for that vacancy, or failing that, shall be filled by the Council.

PAR. 6 A Special Nominating Committee may be organized by any group of one (1) per cent of the membership of the Society in good standing certifying to the Secretary in writing their joint intention to organize such a Committee.

PAR. 7 Within two weeks following the Semi-Annual Meeting, the Regular Nominating Committee shall deliver to the Secretary in writing the names of its nominees for the elective offices to be filled at the next election, together with the written consents of the nominees.

PAR. 8 The names and qualifications of nominees for the various offices proposed by the Regular Nominating Committee shall be published by the Secretary immediately after the receipt of the report of the Nominating Committee.

PAR. 9 Candidates for the office of President and of Vice-President shall be of the grade of Fellow or of Member of the Society. Candidates for all other elective offices may be of any grade of corporate membership.

PAR. 10 Names of any nominees presented by any Special Nominating Committee must be in the hands of the Secretary by the first Tuesday in August of each year, and must be accompanied by the written consent of each nominee.

PAR. 11 On or before the third Thursday in August of each year, the Secretary shall mail to each member entitled to vote a ballot stating the names of the candidates for the elective offices to be filled at the next election.

PAR. 12 Voting for the election of Directors shall close at the City of New York at 10 o'clock in the forenoon on the fourth Tuesday in September in each year, and the ballots shall be canvassed.

PAR. 13 On or before the third Thursday in August of each year, the President shall appoint three (3) Tellers of Election of Directors, whose duty it shall be to canvass the votes cast. The term of office of the Tellers shall expire when their report of the canvass has been presented and accepted.

PAR. 14 By the first day of October, the Secretary shall notify the candidates having the greatest number of votes for their respective offices.

PAR. 15 The Directors shall be declared elected by the Presiding Officer at the Annual Meeting of the Society in December, and their terms of office shall begin on the adjournment of the Annual Meeting.

PAR. 16 If a tie occurs in the vote for any officer, the Presiding Officer at the Annual Meeting shall cast the deciding vote.

PAR. 17 In the election of the Vice-Presidents, three (3) shall be elected every other year and four (4) the alternate years to serve for two (2) years.

PAR. 18 In the election of the Managers, three (3) shall be elected each year to serve for three (3) years.

PAR. 19 A member in office shall not be eligible for immediate re-election to the same office at the expiration of the term for which he was elected, except the Secretary and the Treasurer.

PAR. 20 Members in office shall continue in their respective offices until their successors have been elected or appointed, and have accepted their offices.

ARTICLE R7, ELECTION OF DIRECTORS

RULE 1 The Chairman of the Committee on Local Sections, or in his absence, the senior member of the Committee, shall preside at the Conference of Group Representatives at the time action is taken on the Regular Nominating Committee.

RULE 2 At the business session of the Annual Meeting of the Society, the Chairman of the Committee on Local Sections shall present names recommended by the conference for the Regular Nominating Committee.

RULE 3 The names of the candidates proposed by the Regular Nominating Committee and by any other nominating committee, and the respective offices for which they are candidates, shall be printed in separate lists on the same ballot sheet, each list of candidates to be printed under the names of the members of the particular committee which proposed it.

RULE 4 Each list of names shall contain the name of only one (1) candidate for the office of President. For any other office than President, there may be more than one (1) candidate.

RULE 5 In the election of Directors, the voter shall prepare his ballot by crossing out the name of any candidate or candidates rejected by him and may write in the name of any eligible member of the Society, and shall enclose the ballot in an envelope and seal it. He shall then enclose this envelope in a second envelope marked "Ballot for Directors" and seal it, and he shall then write his name thereon for identification.

RULE 6 The Tellers shall not receive any ballot after the stated time for the closure of the voting.

RULE 7 The Secretary shall certify to the competency and signature of all voters.

RULE 8 The Tellers shall open and destroy the outer envelopes and then open the inner envelopes and canvass the results.

RULE 9 A ballot without the autographic endorsement of the voter on the outside envelope is defective and shall be rejected by the Tellers of Election.

RULE 10 A ballot containing more names than there are offices to be filled is defective and shall be rejected by the Tellers.

RULE 11 In counting the ballots for officers, the Tellers shall consider a ballot for any officer as valid providing the intent of the voter as to that particular office is clear, even though his ballot as to candidates for another office may for any reason be invalid.

ARTICLE C8, OFFICERS

Sec. 1. The Officers of the Society shall consist of the President, the Vice-President, the Secretary, and the Treasurer.

Sec. 2. At its first meeting after the Annual Meeting of the Society the Council shall appoint members of the Society to serve as Secretary and as Treasurer for one (1) year.

Sec. 3. Any vacancy in the office of Secretary or Treasurer shall be filled by appointment by the Council.

B8 OFFICERS

PAR. 1 The Officers shall perform the duties regularly or customarily attaching to their offices under the laws of the State of New York, and such other duties as may be required of them by the Council or the By-Laws.

PAR. 2 In the absence of the President his duties shall be performed by the Vice-President then present, who is serving his second year and is senior by length of membership in the Society, or in his absence or any other disability, by any other member of the Council designated by the Council.

PAR. 3 The Secretary and the Treasurer shall take part in the deliberations of the Council but shall have no vote therein.

PAR. 4 The Treasurer shall be the legal custodian of all funds of the Society. The investment of all trust funds and of other permanent or temporary investment of funds shall be made by the Treasurer with the approval of the Finance Committee and the Council.

PAR. 5 In the absence of the Treasurer his duties shall be performed by any other officer of the Society designated by the Council.

PAR. 6 The Secretary of the Society shall be the Secretary of the Council and of each of the committees.

PAR. 7 The Secretary shall receive a salary which shall be fixed by the Council.

PAR. 8 Any officer may be subject to removal for cause by a vote of fifteen (15) members of the Council at any time, after one (1) month's written notice has been given him to show cause why he should not be removed, and after he has been heard in his own defense, if he so desires.

R8, SECRETARY'S OFFICE

RULE 1 The office of the Secretary shall be open on business days from 9 a.m. to 5 p.m.; on Saturdays from 9 a.m. to 1 p.m.

RULE 2 The Secretary shall establish and enforce rules for the conduct of the business of his office.

RULE 3 The Secretary shall have charge of the rooms of the Society and furnishings, the historical relics and objects of art, and shall make suitable recommendations to the Council for their care and use.

ARTICLE C9, MEETINGS OF THE SOCIETY

Sec. 1. The Annual Meeting of the Society shall be held at such time and place as the Council shall appoint.

Sec. 2. The Semi-Annual Meeting of the Society shall be held at such time and place as the Council shall appoint.

Sec. 3. A special business meeting of the Society may be called at any time and place at the discretion of the Council, or shall be called by the Secretary upon the written request of at least one (1) per cent of the membership.

The call for the meeting shall be issued at least thirty (30) days prior to the date set for it, and shall state the business to be considered. No other business shall be transacted at the meeting.

Sec. 4. There shall be a business meeting of the Society during the Annual Meeting and during the Semi-Annual Meeting. At business meetings fifty (50) corporate members shall constitute a quorum.

Sec. 5. An action of a business meeting of the Society shall be deemed an action of the Society as a whole. Any expenditure required by such action is subject to approval and authorization by the Council.

Sec. 6. A General Meeting of the Society, primarily for the presentation and discussion of technical papers, may be held at such time and place as the Council shall appoint.

ARTICLE B9, MEETINGS OF THE SOCIETY

PAR. 1 A Semi-Annual Meeting shall be held upon the recommendation of the Committee on Local Sections, confirmed by the Committee on Meetings and Program, and authorized by the Council at its regular meeting at the previous Semi-Annual Meeting.

PAR. 2 A General Meeting shall be held upon the recommendation of the Committee on Local Sections, confirmed by the Committee on Meetings and Program, and authorized by the Council.

PAR. 3 Any business meeting of the Society at which a quorum is present may order the submission of any question to the membership for letter-ballot, and the result of the ballot shall be binding.

PAR. 4 Announcements of all Meetings of the Society shall be made in the publications. A notice of each meeting shall be given by the Secretary to each member not less than thirty (30) days before the date of that meeting.

PAR. 5 All Meetings of the Society, except business meetings, shall be in charge of the Committee on Meetings and Program, under the direction of the Council.

ARTICLE R9, MEETINGS OF THE SOCIETY

RULE 1 Subject to the approval of the Committee on Meetings and Program, any Local Sections participating in the conduct of a Semi-Annual or General Meeting shall appoint the necessary special local committees which shall function under the direction of the Committee on Meetings and Program.

ARTICLE C10, PROFESSIONAL DIVISIONS

Sec. 1. The Council may authorize the organization of Professional Divisions composed of members of any or all grades which shall operate under the provisions of the Constitution, By-Laws, and Rules.

ARTICLE B10, PROFESSIONAL DIVISIONS

PAR. 1 The object of each Professional Division shall be to provide, through an organization of members of any or all grades particularly interested in a branch of engineering included in the scope of the Society's activities, means for promoting the arts and sciences of that branch.

PAR. 2 A Professional Division of the Society may be organized upon acceptance by the Council of the written request of a satisfactory number of members. Such a Division shall be designated as the ..... Division of The American Society of Mechanical Engineers.

PAR. 3 The provisions of the Constitution, By-Laws, and Rules of the Society shall cover the procedure of all Professional Divisions, but no action or obligation of a Division shall be considered an action or obligation of the Society as a whole. This By-Law shall be imprinted on any publication issued by a Division.

PAR. 4 For the convenient conduct of its affairs, each Professional Division shall organize an executive committee. The executive committee shall elect its Chairman each year, and upon confirmation by the Council, he shall serve as Chairman of the Division.

PAR. 5 The function of the Standing Committee on Professional Divisions, under the direction of the Council, shall be to organize, foster, and coordinate Professional Divisions and their activities.

PROFESSIONAL GROUPS

PAR. 6 In case the number of members interested in a particular branch of the Society's work is not large enough to warrant the formation of a full Professional Division under the provisions of the By-Laws, the Council may authorize the formation of a Professional Group, and will itself appoint an executive committee to organize such a Group, and will designate the Chairman of the Committee. When a sufficient number of members become attached to this Group, it may petition for reorganization into a Professional Division.

ARTICLE R10, PROFESSIONAL DIVISIONS

RULE 1 When a number of members of the Society interested in a particular branch of the work of the Society favor the formation of a Professional Division for that branch, they may draw up a petition for the establishment of such a Division. Each such petition shall be sent to the Standing Committee on Professional Divisions for presentation to the Council with its recommendation. Upon approval of the petition by the Council, the Chairman of the Standing Committee on Professional Divisions shall appoint a temporary Chairman of the New Division.

RULE 2 The executive committee of each Professional Division shall consist of five (5) members and the term of one (1) member shall expire at the close of each Annual Meeting. The executive committee and such officers as the Division may require shall be selected from the membership of the Society. Other committees, advisors, and associates of the Division shall be appointed by the executive committee as required for a term not exceeding one (1) year.

RULE 3 Upon the organization of a Professional Division the initial selection of the executive committee shall be made by the President upon the nomination of the Standing Committee on Professional Divisions which will state the length of term of each appointee.

RULE 4 During the month of October of each year the executive committee of each Division will nominate to the President through the Standing Committee on Professional Divisions one or more individuals from whom the President shall appoint the member of the executive committee.

RULE 5 The executive committee of each Professional Division shall elect its own officers. No one shall be eligible for chairmanship until he has been a member of this committee for one year, except in the selection of the executive committee for a newly formed Division.

RULE 6 In case of resignation or decease, vacancies shall be filled by appointment of the executive committee subject to the approval of the President of the Society.

RULE 7 The executive committee may, subject to the approval of the Secretary of the Society, appoint or elect a secretary of the Division, who shall report the proceedings of that Division to the Secretary of the Society for notice in the publications. He shall perform the duties of secretary of the Division, and such other duties as may be prescribed by the executive committee.

RULE 8 Any expenditure for the purpose of a Division chargeable to the Society must be authorized by the Secretary of the Society before it is incurred, and must be provided for in the annual budget approved by the Council. Any liability otherwise incurred shall not be binding on the Society, and must be met by the Division itself.

RULE 9 Notice of all Professional Division meetings shall be given in writing to the Secretary of the Society and to the Chairman of the Standing Committee on Professional Divisions at least six (6) weeks in advance of the date set for such meetings.

PROFESSIONAL GROUPS

RULE 10 The functions and responsibilities of a Professional Group shall be the same as those of a Professional Division, except that the Chairman of the executive committee, although having a seat in the conferences of the Chairmen of the Professional Divisions shall have no vote.

RULE 11 The activities of a Professional Group shall be subject to the jurisdiction of the Standing Committee on Professional Divisions.

RULE 12 The Council reserves the right to disband any Professional Group on sixty (60) days' notice.

ARTICLE C11, LOCAL SECTIONS

Sec. 1. The Council may authorize the organization of Local Sections composed of members of any or all grades, which shall operate under the provisions of the Constitution, By-Laws, and Rules.

Sec. 2. The Local Sections shall be associated into geographical groups with annual meetings at which each Local Section shall be entitled to representation. Each geographical group shall be entitled to representation in a subsequent conference of group representatives at the Annual Meeting of the Society.

ARTICLE B11, LOCAL SECTIONS

PAR. 1 The object of a Local Section of the Society shall be to provide means for promoting the work of the Society by a local organization of members who are resident within a given territory.

PAR. 2 A Local Section shall consist of members of any or all grades.

PAR. 3 A Local Section of the Society may be organized upon acceptance by the Council of the written request of a satisfactory number of members. Such a Section shall be designated as the ..... Section of The American Society of Mechanical Engineers.

PAR. 4 The provisions of the Constitution, By-Laws, and Rules of the Society shall cover the procedure of all Local Sections, but no action or obligation of a Section shall be considered an action or obligation of the Society as a whole. This By-Law shall be imprinted on any publication issued by the Section.

PAR. 5 For the convenient conduct of its affairs, each Section shall organize an executive committee.

PAR. 6 The affairs of the Local Sections shall be in general charge of the Standing Committee on Local Sections, under the direction of the Council.

PAR. 7 The Council of the Society, on sixty (60) days' notice, may suspend or disband any Local Section.

PAR. 8. There shall be a group meeting of Local Section delegates of each group preferably between October fifteenth and November fifteenth of each year at some central point within the geographical limits of the group.

PAR. 9 Each Local Section shall be entitled to one voting delegate in the group meeting of Local Section delegates. In addition to such delegates the group representative serving his second year shall serve as chairman of the group meeting, but shall vote only in case of a tie.

PAR. 10 At such group meeting of Local Section delegates, one representative shall be elected to represent the group for two (2) years at the conference of group representatives.

PAR. 11 There shall be a conference of group representatives each year at the place and at the time of the Annual Meeting of the Society. There shall be sixteen (16) representatives to such annual conference, two (2) from each of the eight (8) groups, which groups shall conform geographically to those provided for in Article B7, Par. 3.

ARTICLE R11, LOCAL SECTIONS

RULE 1 When a number of members of the Society in any territory within the limits of North America, Hawaii, Puerto Rico and Cuba favor the formation of a Local Section in that territory, a preliminary meeting shall be called and notice sent to the entire membership of the Society residing in that territory. At this meeting a petition for the formaton of a Local Section, containing suggestions as to the territory to be included in the Section, may be presented, and, if adopted, shall be sent to the Standing Committee on Local Sections for recommendation to the Council.

RULE 2 Upon the approval by the Council of the petition, a meeting of the signers shall be held for the selection of a temporary executive committee of at least five (5) members. This committee shall have charge of, and be responsible for, the proceedings of the Local Section until the next election of officers.

RULE 3 The executive committee of a Local Section shall consist of a chairman, a secretary, and such other officers as may be found desirable. Such officers shall be elected by ballot of the members of the Society constituting the Section. The committee shall be elected before the first day of June each year and shall take office on the first day of July.

RULE 4 A member of the Society shall be entitled to vote or to hold office in not more than one (1) Local Section at a time.

RULE 5 The chairman of each Local Section shall have the privilege of attending all meetings of the Standing Committee on Local Sections.

RULE 6 The secretary of each Local Section shall report the proceedings of that Section to the Secretary of the Society for notice in the publications. He shall discharge the duties of secretary of the Section, and such other responsibilities as may be prescribed by the executive committee.

RULE 7 Any expenditure chargeable to the Society for the purpose of any Local Section must be provided for in the annual budget approved by the Council. No liability otherwise incurred shall be binding upon the Society.

RULE 8 Each Local Section shall use only such uniform stationery as is supplied by the Secretary of the Society.

RULE 9 For the convenient cooperation between the Local Sections and the Professional Divisions, each Local Section may appoint an individual or a committee to act as a correspondent with each Professional Division, with duties that will comprise generally the arranging with the Professional Division for the presentation of papers, holding of meetings, etc., within that particular Local Section, and as far as possible, to act as a means of furnishing information, secured within the Local Section, which might prove of interest to the Division.

RULE 10 A Local Section may affiliate with existing local engineering organizations, or form jointly with them new local engineering organizations, but the plan of such affiliation or organization, and the obligations assumed by the Local Section and the Society thereby, shall first be approved by the Council on recommendation of the Committee on Local Sections. Any expenditures incurred in such an affiliation shall be binding only on the Section and not on the Society as a whole.

RULE 11 A Local Section may arrange to hold joint meetings with other engineering organizations and may invite members of such organizations to attend its meetings, but all expenses incurred shall be binding only on the Section and not on the Society as a whole.

RULE 12 Each Local Section may adopt its own by-laws, for the conduct of its affairs, provided such are in harmony with the Constitution, By-Laws, and Rules of the Society, and provided also every publication of such by-laws be prefaced with a copy of this Rule.

RULE 13 Groups of members residing outside the limits of North America, Hawaii, Puerto Rico, and Cuba may engage in group activities with local members of the A.S.C.E., A.I.M.E., and A.I.E.E., in which case the Council may grant them nominal financial support, provided such group action is not in conflict with the policies and activities of any established national engineering societies in such foreign countries, and that such groups cooperate as permitted with such foreign societies.

ARTICLE C12, STUDENT BRANCHES

Sec. 1. The Council may authorize the organization of Student Branches which shall operate under the provisions of the Constitution, By-Laws, and Rules.

ARTICLE B12, STUDENT BRANCHES

PAR. 1 A Student Branch may be organized upon acceptance by the Council of the written request of at least fifteen (15) senior and junior students in any engineering school of accepted standing. Such a Branch shall be designated as the .... Student Branch of The American Society of Mechanical Engineers.

PAR. 2 The provisions of the Constitution, By-Laws, and Rules of the Society shall cover the procedure of all Student Branches, but no action or obligation of a Student Branch shall be considered an action or obligation of the Society as a whole. This By-Law shall be imprinted on any publication issued by the Student Branch.

PAR. 3 The function of the Standing Committee on Relations With Colleges under the direction of the Council shall be to organize, foster, and govern Student Branches and their activities.

PAR. 4 Annual regional conferences of delegates from Student Branches shall be held at the discretion of the Committee on Relations with Colleges.

ARTICLE R12, STUDENT BRANCHES

RULE 1 Upon the recommendation of a Student Branch, the President of the Society shall designate a corporate member of the Society as Honorary Chairman for one (1) year, to be a member ex officio of the governing body of the Student Branch.

RULE 2 Annually, each Student Branch shall select officers including a chairman and a governing body of at least three (3) Student-members.

ARTICLE C13, PUBLICATIONS AND PAPERS

Sec. 1. The papers and publications of the Society shall be issued in such manner as the Council may direct.

ARTICLE B13, PUBLICATIONS AND PAPERS

PAR. 1 All publications of the Society shall be in charge of the Standing Committee on Publications, under the direction of the Council.

PAR. 2 The publications of the Society shall consist of (*a*) the Transactions of the Society; (*b*) Mechanical Engineering; and (*c*) such other publications as the Council may direct.

PAR. 3 The policy of the Society shall be to give papers read before it the widest publicity.

PAR. 4 The Society shall not be responsible for statements or opinions advanced in papers or in discussion at meetings of the Society or of its Divisions or Sections, or printed in its publications.

PAR. 5 The Society reserves the right to copyright, at the discretion of the Council, any of its papers, discussions, reports, or publications.

ARTICLE C14, FUNDS

Sec. 1. The deposit, investment, and disbursement of all funds shall be subject to the direction of the Council.

ARTICLE B14, FUNDS

RECEIPTS

PAR. 1 All funds shall be paid in to the Secretary, who shall enter them in the books of the Society, and deposit them to the account of the Treasurer in a bank designated by the Council.

PAR. 2 All bills against members and others shall be made and collected by the Secretary.

PAR. 3 Income from initiation fees shall not be used for current expenses. At the close of each fiscal year, unless the Council then orders otherwise, this income shall be added to surplus.

PAR. 4 Funds may be solicited from sources outside of the Society for the conduct of research. All contributions to the Society for any specific purpose shall be disbursed under the direction of the Council.

PAR. 5 All gifts or bequests not designated for a specific purpose shall be invested and only the income shall be used.

PAR. 6 All gifts or bequests to the Society designated by the donors for a specific purpose, and all moneys permanently set aside by the Council for specific purposes, shall be invested and either the capital or income as so designated shall be used for that specific purpose for which it was designated.

PAR. 7 Except where otherwise definitely specified in a gift or bequest, the Secretary of the Society shall at the close of each fiscal year compute the interest and return received for the year on the Society's invested funds. The Secretary shall determine an average rate of income and shall recommend an apportionment of such return to each of the several funds for which investment is made. Upon approval and order of the Council these apportioned returns shall be duly entered in the books of account of the Society as the income for the year on the various funds.

PAR. 8 At the discretion of the Council income from any fund may be allowed to accumulate for expenditure in any subsequent year, or the income may be added to the original fund and invested with it. But in no case shall money be expended from such specially designated funds, either from capital or from income duly apportioned as detailed in paragraph 7, for the current expenses of the Society.

PAR. 9 Upon the maturity of any permanent investment the Treasurer shall reinvest such funds subject to approval by the Finance Committee and the Council.

PAR. 10 The securities of the Society, either principal or trust funds, may be sold, bought, or exchanged upon the written order of the Treasurer, the Secretary, and the Chairman of the

Finance Committee, and these three signatures must appear on any order to any broker, bank, or company. If any one or two of these officers be temporarily unavailable, then an equal number of members of the Executive Committee may be substituted.

Expenditures

Par. 11 All expenditures shall be made in accordance with the budget of appropriations as adopted by the Council.

Par. 12 Any obligations which may be incurred during the fiscal year and which will require the expenditure of the Society's funds outside of appropriations made by the Council shall first be referred to the Finance Committee for report by that Committee back to the Council.

Par. 13 The Secretary shall report to the Finance Committee each month the total expenditures incurred against each appropriation, together with the amount of each appropriation which is unexpended.

Par. 14 The annual appropriations approved by the Council, or so much thereof as may be required for the work of the Society, shall be expended by the Secretary, under direction of the committees.

Par. 15 All bills against the Society shall be in charge of the Secretary. Upon competent certification as to correctness and proper authorization, payment shall be made by the Secretary from the Cashier's Account.

Par. 16 The Treasurer shall reimburse the Cashier's Account for payments made therefrom only upon orders duly signed by the Secretary and the Chairman of the Finance Committee.

Article R14, Funds

Rule 1 The accounts of the Society shall be audited and approved annually by a chartered or other competent public accountant.

Rule 2 The Finance Committee shall hold monthly meetings for such business as shall come before it.

Rule 3 Each year the Finance Committee shall present with its report a detailed estimate of the probable income and expenditures of the Society for the following twelve (12) months.

Rule 4 Any contract or other obligations to pay money in the Society's work shall be valid only when signed by the Secretary.

Article C15, Professional Practice

Sec. 1. In all professional and business relations the members of the Society shall be governed by the Code of Ethics incorporated in the By-Laws.

Sec. 2. Any member who has violated the Constitution of the Society, or who is guilty of conduct rendering him unfit to remain a member, may be expelled by the vote of fifteen (15) members of the Council, after he has been given opportunity to be heard in his own defense.

Article B15, Professional Practice

Par. 1 All members of the Society shall subscribe to the following Code of Ethics, as required by the Constitution:

A Code of Ethics for Engineers

That the dignity of his chosen profession may be maintained, it is the duty of every engineer

1 To carry on his professional work in a spirit of fairness to employees and contractors, fidelity to clients and employers, and devotion to high ideals of personal honor.

2 To refrain from associating himself with, or allowing the use of his name by, any enterprise of questionable character.

3 To treat as confidential his knowledge of the business affairs or technical processes of clients or employers when their interests require secrecy.

4 To inform a client or employer of any business connections, interests, or affiliations which might influence his judgment or impair the disinterested quality of his services.

5 To accept financial or other compensation for a particular service from one source only, except with the full knowledge and consent of all interested parties.

6 To advertise only in a dignified manner, to refrain from using any improper or questionable methods of soliciting professional work, and to decline to pay or to accept commissions for work secured by such improper or questionable methods.

7 To refrain from using unfair means to win professional advancement and to avoid unfairly injuring another engineer's chances to secure and hold employment.

8 To cooperate in building up the engineering profession by the interchange of general information and experience with his fellow engineers and with students of engineering and also by contributions to the work of engineering societies, schools of applied science, and the technical press.

9 To interest himself in the public welfare and to be ready to apply his special knowledge, skill, and training in the public behalf for the use and benefit of mankind.

Article R15, Professional Practice

Rule 1 The Standing Committee on Professional Conduct, having in charge all matters connected with the Code of Ethics and its enforcement, shall cooperate with similar committees of other societies.

Rule 2 The Standing Committee on Professional Conduct shall follow the procedure below in considering cases presented to it:

(*a*) Cases for consideration may be:

(1) An interpretation of the code, or
(2) Rendering an opinion on the questionable conduct of a member of the Society.

(*b*) Cases and complaints are to be submitted to the Committee by the Secretary of the Society.

(*c*) Before a case is submitted to the Committee, the Secretary of the Society shall ascertain whether the person against whom a complaint has been made is a member of the Society, and if possible decide whether the case is of such importance as to be passed on by the Committee, or is of such a trivial nature that it can be handled by the Secretary.

(*d*) A case may be submitted by the Secretary of the Society either through the Chairman or jointly to each member of the Committee.

(*e*) On receipt of a case the Committee shall decide whether it can best make a finding by correspondence, or by a meeting of the Committee, and whether hearings shall be given to the interested parties.

(*f*) The Committee may appoint subcommittees to consider and report on cases too remote for the main Committee to act upon.

(*g*) All correspondence from members of the Committee should pass through the office of the Chairman of the Committee and not be sent direct to the Secretary of the Society. In order to facilitate filing and preparation of reports, a letter should cover only one case or subject.

(*h*) Reports and findings on cases shall be sent by the Chairman to the Secretary of the Society for consideration by the Executive Committee or Council of the Society, which may approve the findings or take such other action as may seem desirable or necessary.

(*i*) The Committee may, if it so desires, suggest action by the Executive Committee or Council.

(*j*) The Council shall have the power on recommendation of the Committee on Professional Conduct, either (1) to censure by letter the conduct of a member who has acted contrary to the Code, if the breach is of a minor character, or (2) to cause the member's name to be stricken from the rolls of the Society, as provided in C15, Sec. 2.

Article C16, Amendments to the Constitution

Sec. 1. At any Meeting of the Society any person entitled to vote may propose in writing an amendment to this Constitution, provided that it shall bear the written indorsement of at least twenty (20) corporate members in good standing.

Such proposed amendment shall not be voted on for adoption at that meeting, but shall be open to discussion and modification, and to a vote as to whether, in its original or modified form, it shall be mailed in printed form to the members of the Society for action.

If the members present at the meeting, not less than twenty (20) voting in favor thereof, shall so decide, then

the Secretary shall mail in printed form to each person entitled to vote, at least sixty (60) days previous to the next Meeting of the Society, a copy of the proposed amendment as so decided by said vote, accompanied by any comment the Council may elect to make.

A ballot shall be sent with the proposed amendment, and the voting shall be by sealed letter-ballot, closing at noon of the twentieth (20th) day preceding the meeting of the Society following the mailing.

The adoption of the amendment shall require a vote in its favor of two-thirds of the votes cast.

The Presiding Officer at the meeting of the Society following the close of the ballot shall announce the result, and if the amendment is adopted it shall thereupon take effect.

Sec. 2. Any changes in the order or numbering of paragraphs of the Constitution, By-Laws, and Rules required by an amendment shall be made under the direction of the Council.

Sec. 3. This Constitution shall supersede all previous rules of the Society, and shall go into effect upon the adjournment of the meeting of the Society at which the presiding officer announces its adoption.

Article B16, Amendments

Par. 1 At least fourteen (14) days before the closing of a ballot on an amendment to the Constitution, the President shall appoint three (3) Tellers whose duty it shall be to canvass the votes cast.

Par. 2 The Tellers shall canvass the ballots and shall certify the result to the Presiding Officer at the meeting of the Society at which the result is to be announced.

Par. 3 In the case of a tie vote on an amendment, the Presiding Officer at the Meeting of the Society shall cast the deciding vote.

Par. 4 The terms of office of the Tellers shall expire when their report of the canvass has been presented and accepted.

Par. 5 At any regular meeting, the Council may, by a two-thirds vote of its members present, adopt, or amend By-Laws in harmony with the Constitution, provided that such By-Laws or amendments shall have been submitted in writing at a previous meeting of the Council and the Secretary has mailed a copy to each member of the Council at least fifteen (15) days before the meeting at which action is to be taken. A By-Law or an amendment to a By-Law shall take effect immediately upon its adoption by the Council, and shall be published at once by the Secretary to all members of the Society.

Par. 6 At any regular meeting, by a majority vote of its members present, the Council may adopt or amend Rules in harmony with the Constitution and the By-Laws. A Rule or an amendment shall take effect immediately upon its adoption by the Council, and shall be published by the Secretary to all the members of the Society.

Article R16, Amendments

Rule 1 In voting on an amendment to the Constitution the voter shall prepare his ballot by crossing out that part of the amendment which he wishes to vote against. He shall then enclose the ballot in an envelope and seal it, and shall enclose this envelope in a second envelope marked "Ballot on Amendment" and seal it, and he shall then write his name thereon for identification.

Rule 2 The Tellers shall not receive any ballot after the stated time for the closure of the voting.

Rule 3 The Secretary shall certify to the competency and signature of all voters.

Rule 4 The Tellers shall open and destroy the outer envelopes and then open the inner envelopes and canvass the results.

Rule 5 A ballot without the autographic endorsement of the voter on the outside envelope is defective and shall be rejected by the Tellers.

Rule 6 The Tellers shall consider a ballot as valid provided the intent of the voter is clear, and provided also that he conforms with the regulations for voting.

SOCIETY RECORDS—Part 3

Parts 1 and 2 of Society Records for the year 1942, containing Council and Committee personnel and other general information, the directory of members, and the Constitution, By-Laws, and Rules, were issued as Section Two of the Transactions for February, 1942. Part 3 is published for inclusion with all bound copies of Volume 64 of the Transactions and distributed to members of the Society upon request.

OCTOBER, 1942

Memorial Biographies

THE purpose of Memorial Biographies is to place on permanent record the biographical and professional data relating to deceased members of The American Society of Mechanical Engineers. Hence every effort is expended to insure accuracy and to make the memorials as inclusive as is reasonably possible.

The first source of information upon which these notices are based is the Society's file of membership applications and transfers. In the case of the more recent members, these application records are fairly complete. The applications of those who became members many years ago, however, contain less detailed data, and in many cases the sponsors are no longer alive, so that assistance from this source cannot always be obtained. If the member has been retired for several years prior to his death, his business associates are frequently hard to locate, and, in some cases, members of his family cannot be found. While all these factors add to the difficulty of obtaining accurate and fairly complete data, every possible source of information is explored, with the result that publication of the notice is delayed. Nearly all of the memorials in this issue have been prepared under these difficulties.

It is the practice of the Committee on Publications in the case of some deceased members to ask former friends and associates to prepare the obituary. The object is to secure a final record that will be more valuable for having been prepared by men who knew the deceased and are competent to evaluate his work. Memorials prepared in accordance with this policy are signed by those who wrote them or who collaborated in their preparation. To all persons who have thus co-operated, the Committee acknowledges its gratitude.

The Committee also appreciates and acknowledges the assistance that has been given by relatives, business associates, and friends in the preparation of all other memorials. It also acknowledges its debt to such sources as Who's Who in Engineering, Who's Who in America, and similar publications; the Encyclopedia of American Biography, and the National Cyclopedia of American Biography; the technical and daily press; colleges and universities and their alumni associations; and engineering and other societies which have supplied information from their records.

Relatives, business associates, and Local Section and Student Branch officers are urged to notify the Society promptly of the deaths of members. Newspaper clippings or obituaries in any other form should be sent whenever available and the names and addresses of those who can supply further information should be furnished. A special form for supplying complete details will be forwarded by the Office of the Society upon request.

THE COMMITTEE ON PUBLICATIONS

Memorial Biographies

EDWARD THOMAS ADAMS (1861–1939)

Edward Thomas Adams, a member of the A.S.M.E. since 1899, died in Los Angeles, Calif., on June 24, 1939, of coronary thrombosis. He had carried on a consulting practice in that city since 1919, specializing in the design of oil-well pumps and small Diesel engines, on which he had taken out a number of patents.

Mr. Adams was born on December 4, 1861, in Ohio, at Hampden, Geauga County, son of Edward Francis and Roah Elmira (Shattuck) Adams. His early education was obtained chiefly in schools in Chicago, Ill., then he spent about ten years, 1880–1890, on the Pacific Coast. During this period he was variously engaged as draftsman, millwright, and patternmaker with different firms, including the W. A. Woods Manufacturing Co., Santa Cruz Iron Works, and Gillispie Lumber Company (companies no longer existent); for two seasons he operated a mill in the redwood district.

In the years 1889 to 1891 he helped to establish and was in charge of a course of instruction in mechanical drawing in the city schools of Stockton, Calif. Subsequently he took two years' work in the Civil Engineering Department of Leland Stanford Junior University and in 1894 secured an M.E. degree from Cornell University. He worked as a draftsman for the Payne Engine Company, Elmira, N.Y., 1894–1895, then served as instructor in the Department of Mechanical Engineering at Cornell, 1895–1897, receiving his M.M.E. there in 1896.

After working as mechanical engineer for the Bullock Manufacturing Company for a year, Mr. Adams went into the Engineering Department of the Edward P. Allis Co., Milwaukee, Wis., in 1898, serving as private draftsman or assistant to Edwin Reynolds (Member A.S.M.E., president in 1902), general superintendent of the company. When the company was reorganized in 1901, Mr. Adams was made mechanical engineer of the Allis-Chalmers Company, and several years later he became manager and chief engineer of the Gas and Mill Engine Department. He designed and installed engines for various companies, including the Westinghouse company at Pittsburgh, Pa., and the Allis-Chalmers company at Milwaukee. Among these engines were those built for the U.S. Steel Corp., at Gary, Ind., said to be the largest gas engines, at that time, in the world.

Mr. Adams left the Allis-Chalmers Company in 1910 and subsequently served as president of the Wisconsin Engine Company, Corliss, Wis., and as chief engineer of M. Rumely Co., La Porte, Ind. In 1917–1918 he was consulting engineer for the Humphrey Gas Pump Company, Syracuse, N.Y. He then went to the West Coast and after some work for the Doble Laboratory, steam automobile engineers, in San Francisco, established his office as consulting engineer in Los Angeles.

Mr. Adams became a member of the A.S.M.E. in 1899. He served on a special committee of the Society on Power Tests from 1912 until 1918 when the committee organization for this work was revised. Mr. Adams was appointed a member of both the Main Committee and Individual Committee No. 17 on Gas and Oil Engines and he served on the Main Committee for five years and on No. 17 until April, 1928. He belonged to the University clubs in Milwaukee and Chicago and was a member of the Sigma Xi fraternity.

Mr. Adam's wife, Ester A. (Boschen) Adams, whom he married in 1891, died in 1931. He was survived by four daughters and two sons, as follows: Roah (Mrs. John Nahapiet) and Marion (Mrs. Raymond Sullivan), of San Francisco, Calif.; Adelaide (Mrs. Marshall Williams), of San Fernando, Calif.; Helen (Mrs. Thos. Monroe), of Tucson, Ariz.; and Thomas E. and E. Ernest Adams, of Los Angeles.

LEON PRATT ALFORD (1877–1942)

Leon Pratt Alford came of colonial ancestry on both sides. He was born at Simsbury, Conn., on January 3, 1877. His father was Emerson Alford, a manufacturer at Collinsville, Conn., and his mother Sarah Merriam (Pratt) Alford.

He prepared for college at the Plainville (Conn.) High School, learning the trade of house carpenter during his vacation periods. He was graduated at the Worcester Polytechnic Institute in 1896, with a high scholarship record, as a B.S. in E.E. when only nineteen years old. In 1905 he received a degree in M.E.

He married Grace Agnes Hutchins of Templeton, Mass., on January 1, 1900, and had one son Ralph I. Alford, a doctor in Montclair, N.J., and two grandchildren. He lived for the first ten years after graduation in various places about Boston, but throughout mid and later life his home was in Montclair.

Upon graduation in 1896 Alford entered the employment of the McKay Metallic Fastening Association at Winchester, Mass., where he secured his shop and drafting room experience. During the reorganization and consolidation of this and other companies engaged in the manufacture of boot and shoe machinery he rose from assistant machine-shop foreman to general foreman, assistant superintendent, and production superintendent of the various McKay companies which united to form part of the United Shoe Machinery Company. In April, 1902, he became division engineer and assisted in the designing and building of the United Shoe Machinery Plant at Beverly, Mass., at that time the largest reinforced-concrete machine shop in the world. Alford was responsible for much of the design and installation of the machinery and equipment, and for the general details of the buildings. In 1904 he became assistant mechanical engineer and in January, 1906, chief of the mechanical engineering department.

In 1907 his lifework took a different direction, for in that year he became an editor of the *American Machinist* and was made editor-in-chief in 1911. During his editorship the *Machinist* maintained and advanced its high position in its field. When he resigned this post in 1917 he wrote a friend that he was "through with journalism," but within a few months he became editor of *Industrial Management*. In July, 1921, he joined the Ronald Press Company and was editor of the journals in the management field which under several changes of name, *Management Engineering, Management and Administration*, etc., were published by that company until the merger of the magazine with *Factory and Industrial Management* in 1929. In 1925 Alford was elected director of the company and continued on its board until his death. He was vice-president from 1926 to 1937. In these capacities he headed up the editorial policies of the company.

His influence on the literature of management was far-reaching. He planned and edited "Management's Handbook," which became the standard reference book in that field, not only in this country but in England and Germany. With rare ability he drew together the experience and knowledge of other people and co-ordinated them into a complete whole. Through the books which he edited and those he wrote himself he rendered a distinguished service to the engineering field—the more so since the engineer engaged in management work has had far less reference literature to guide him than has the engineer engaged in other branches of engineering work.

In addition to editing "Artillery and Artillery Ammunition," 1917, "Management's Handbook," 1924, and "Cost and Production Handbook," in 1934, Alford was the author of "Bearings and Their Lubrication," 1911. His paper on "The Laws of Manufacturing Management" before the A.S.M.E. in 1927 won him the first award of the Melville Medal, and appeared in 1928 in book form and had a wide sale. He also wrote the "Life of Henry Laurence Gantt," 1934, and "Principles of Industrial Management for Engineers," 1940.

His contributions to the papers and reports of the A.S.M.E. are too many to be enumerated here in full. Outstanding among them is the series of progress reports on management. The first one in 1912, "The Present State of the Art of Industrial Management," was written for a committee of which he was secretary. A further review on "The Status of Industrial Relations" was prepared in 1919 at the request of the Committee on Meetings and Program. These were so successful that he wrote a continuation in 1922, "Ten Years' Progress in Management," and another with the same title in 1932. It was hoped that he might write a fourth one in 1942, but this was cut short by his death. His outstanding paper on the "Laws of Manufacturing Management" has been mentioned. The range of his papers included high-speed drilling, industrial relations, preferred numbers, factory construction and arrangement, production control, and a series of papers with J. E. Hannum on evaluating manufacturing operation, suggesting the "kilo man-hour" as the measuring unit. In addition to all these he wrote papers for the S.P.E.E., A.M.A., and the American Engineering Council, and others given in England, Japan, and Germany.

Valuable as were his contributions to the publications of the A.S.M.E., his work on its various committees was even more outstanding. Probably no one in all its membership had a longer and more varied service. There was no time from 1913 until his death that he was not serving on some committee, on the Council, or as A.S.M.E. representative on other bodies. The mere list of these assignments covers more than a closely typewritten page.

He served on most of the standing committees and on many special ones, of most of which he became chairman. The standing committees included those on Constitution and By-Laws, Professional Divisions, Meetings, and Honors and Awards. He had been a member of the executive and other committees of the Management Division, and

of many special committees dealing with research and technical problems, the Aims and Organization of the Society, Policies and Budget, and Administration, and he represented the Society on the American Engineering Council, Gantt Medal Board, National Management Council, etc.

No one can speak of Alford's work on the American Engineering Council with more authority than L. W. Wallace, executive secretary of the Council throughout most of its existence. He says, "Mr. Alford was for many years a member of the A.S.M.E. delegation and during much of the time was vice-chairman of the delegation. He attended the organization meetings of the Council, served on the committee which drafted its constitution and by-laws, and acted as temporary executive secretary for about three months, until I took over in April, 1921.

"Alford was a member of the Committee on Elimination of Waste in Industry, the first important study the Council made. He also contributed markedly to planning the study, conducting it, and especially the editing of the report, 'Waste in Industry.' He was one of the strong supporters of that report when it was adopted by the Administrative Board of the Council in June, 1921. He was also a member of the Committees on the Twelve-Hour Shift in Industry, on the Balance of Economic Forces, and on Safety and Production, and edited these reports. He was chairman of the original Committee on Publicity and Publications and served on it for many years. He also served for many years on the Public Affairs Committee and several times was its chairman. He was repeatedly a member of the Executive Committee and was on many of its subcommittees.

"Throughout the life of American Engineering Council no man served it in more capacities, or with greater courage, loyalty, and ability than did L. P. Alford. To it he gave unstintingly of his time, energy, and balanced judgment because of his belief in it as an instrument of public service."

His connection with the Council brought him into contact with various government problems as a consulting engineer. A study which he made in 1935 for the Textile Labor Relations Board led to a much more extended one on the manufacturing costs of telephone apparatus and equipment which he made for the Federal Communications Commission during 1935–1937, as a basis for recommendations on rates. The study reviewed the history of the Western Electric Company and its relation to the telephone industry; and made an examination of its cost and accounting procedures and those of its competitors, and an appraisal of its cost accounting practice. This report was made a part of the Commission's report to Congress.

With the completion of this work for the government, in 1937, Alford became professor of administrative engineering in New York University, and head of the Industrial (later Administrative) Engineering Department, which position he held until his death. He undertook this work with some hesitation, but on the advice of friends long experienced in this field who knew the man and assured him that as editor he had been teaching for thirty years. He fully justified this judgment and was happy in the work. He taught courses in management, industrial economics, etc., to seniors and graduates. His last book, "The Principles of Industrial Management for Engineers," published in 1940, was an outcome of this work. His long experience, wide contacts, and even wider viewpoint give it special value and it has taken its place among the standard textbooks in that field.

For some years he had been warned of heart trouble, but continued his work much as usual until his last brief illness. He died in the Flower Memorial Hospital in New York on January 2, 1942. It is characteristic of him that, quickly and unexpectedly as the end came, his immediate tasks were in order and the remaining lectures of his courses were written in anticipation of a rest he was planning to take.

Alford joined the A.S.M.E. as a junior member in 1900. He was elected a member in 1908 and a Fellow in 1936. He was vice-president from 1920 to 1922, and because of his long and distinguished service in the Society he was awarded honorary membership in 1941, only a month before his death. In 1932 the Worcester Polytechnic Institute conferred on him the honorary degree of Doctor of Engineering in recognition of his work in connection with machine tools.

He was a member of the American Management Association, the S.P.E.E., National Association of Cost Accountants, the Institut Scientifique d'Organisation et de Gestion, the Engineers' Club, New York, and Sigma Xi. He received the first award of the Melville Medal in 1927 and the Gantt Medal in 1931.

Alford's wide influence was not based so much on creative contributions, such as those of Taylor, Gantt, and Gilbreth, as on his singular clarity, breadth of view, and on his balance of judgment and capacity to see things as a whole and in true proportion. His writings were seldom the object of controversy because his presentations were so well grounded they found general acceptance. His handbooks were successful because they were well balanced, authoritative and helpful.

The A.S.M.E. has had few members who have given it more useful service. His presence on any committee strengthened it. It was especially valuable where the matter under consideration was controversial or confused. In discussion he was slow to speak, convincing, and apt to reserve comment until all points had been discussed. Then he would summarize the situation, and final action would often crystallize around his suggestions.

He stimulated and directed much valuable work by other men. The present writer acknowledges his debt to him. He was on the A.S.M.E. trip to Germany in 1913. At the close of the trip at Munich, Alford, impressed with the technical progress in Germany, proposed the writing of a series of articles on tool building and the development of machine tools, which started a life interest in that field.

His friends will long remember the quiet voice, the kindly eyes smiling behind his glasses, his friendliness and wise counsel. It is such men as he who have made the A.S.M.E. what it is. We are glad the Society's highest honor came to him in time for him to enjoy it. It must have meant much to one who had given so much.—[Memorial prepared by JOSEPH W. ROE, Southport, Conn. Fellow and Melville Medalist, A.S.M.E.]

DUDLEY BAIRD (1877–1939)

Dudley Baird, vice-president of the Pacific Foundry Company, Ltd., San Francisco, Calif., had been connected with that company more than thirty years when his death occurred on October 17, 1939. He entered its employ early in 1907 to design and erect chemical and metallurgical apparatus, and advanced through the position of secretary to the office of vice-president, in charge of engineering and operations.

Mr. Baird was born at Oakland, Calif., on February 14, 1877, his parents' names being Andrew and Julia Courtis Baird. After securing a B.S. degree at the University of California in 1898 he spent a year in postgraduate work in mining and metallurgy. During the following year he worked successively as stationary engineer in the steam-electric power plant of the Tesla (Calif.) Coal Mining Company, stamp mill assistant at Chips Mine, Sierra City, Calif., and chairman with a surveying party in Nome, Alaska.

After his return to California in August, 1900, he took a position with the Penn Mining Company, Campo Seco, Calif., as assayer and chemist. He was promoted to smelter superintendent and metallurgist in a few months and continued in that capacity for four years. Among other duties he was responsible for the design, erection, and operation of additional smelting, roasting, and ore-crushing units. In 1905–1907, prior to his connection with the Pacific Foundry Company, he was engaged with the erection and operation of a smelter for the Union Copper Mining Company, at Copperopolis, Calif.

Mr. Baird held many patents on multiple-hearth furnaces for roasting, calcining, and incinerating. He had been a member of the A.S.M.E. since 1921 and also belonged to the American Institute of Mining and Metallurgical Engineers and the Engineers Club of San Francisco. He married Viola Brainerd, of Middlebury, Vt., in 1910 and is survived by her and a son, Robert Baird.

JOHN JOSEPH BAKRADZE (1889–1937)

John Joseph Bakradze, whose death occurred in St. Luke's Hospital, New York, N.Y., on November 20, 1937, was born on January 1, 1889, at Vladikaukas, Russia. He secured his early education in that country and subsequently studied mechanical engineering in Germany. After returning to Russia in 1910, he was employed successively as a draftsman by Greefits & Co., Baku, as installation engineer by the Technical Bureau, Armavir, and the International Harvester Company of America, at Riga, and as engineering inspector in the car division of the Russian Army.

In 1920 he went to Constantinople, Turkey, where he was engaged by the Standard Oil Company as chief engineer on one of its barges. He came to the United States in the early part of 1923 and spent brief periods with the White Motor Car Company, on Long Island, and as draftsman for the Lutz Elevator Co., Inc., New York Edison Company, and the firm of Eadie, Freund & Campbell, all in New York.

Mr. Bakradze's work since 1924 had been with the firm of Sprague & Slocum and its successor, Slocum & Fuller, New York. First as draftsman and later as mechanical engineer, he was engaged in the field of heating and ventilating, and electric wiring, in connection with building construction. Since the reorganization of the firm in 1931 he had not been continuously employed.

Mr. Bakradze became an associate member of the A.S.M.E. in 1924 and was automatically transferred to the grade of member in 1935. He is survived by his widow, Pauline (Lobutzky) Bakradze.

OSCAR HOWARD BALDWIN (1863–1940)

Oscar Howard Baldwin, a member of the A.S.M.E. since 1889, died at his home, "Fairmount," Salcombe, South Devon, England, on February 14, 1940. He was born on November 4, 1863, in Newark, N.J., and was graduated from the Stevens Institute of Technology in 1885 with a degree in mechanical engineering. The following account of his work is taken from *The Engineer*, February 23, 1940.

"After serving a short time with the Pennsylvania Railway, he joined the firm of Westinghouse, Kerr and Co., which later became the Westinghouse Electric and Manufacturing Company. After being chief engineer in the lighting plant of Plainfield, N.J., for a year, he rejoined the Westinghouse Electric and Manufacturing Company and was chosen by the late George Westinghouse to look after its British interests. From 1889 to 1893 he was engineer of the Westinghouse Electric Company of London, and had charge of the engineering work of the firm, including the erection of the new plant at the Sardinia Street Station of the Metropolitan Electric Supply Company. In 1893 he returned to America for a year to take charge of the electrical exhibit of the Westinghouse Company at the World's Fair, and a year later was given charge of the foreign sales department of the company. About 1898 the offices of the Westinghouse Electric Company, Ltd., of London were established at 2, Norfolk Street, Strand, and Mr. Baldwin became the managing director of the firm. From 1900 to 1902 he was managing director of J. and G. White and Co., Ltd., of London. Eventually the Westinghouse Electric Company, Ltd., of London, became the British Westinghouse Electric and Manufacturing Company, Ltd., and works were built at Trafford Park, Manchester. Mr. Baldwin remained at the London office of the firm and became the district manager of the company. When the name of the company was changed to the Metropolitan Vickers Electrical Company, Ltd., he still remained at the London office, and for some years he was also joint European manager of the Westinghouse Electric International Company. He retired about 1920, and for a time went to live at Salcombe, South Devon. In 1927 he was entrusted by the Taylor Stoker Company, of America, with the management of its interests in England, and when the British company was formed he became director in London. Mr. Baldwin remained a director of the company till he finally retired in 1933."

HAROLD BUTLER BARNES (1880–1938)

Harold Butler Barnes was born at Springfield, Ill., on February 18, 1880, son of Phineas and Fanny (Ellsworth) Barnes. He took private tuition and attended the Thurston Preparatory School in Pittsburgh, and at the age of fourteen passed the entrance examinations for the engineering course at the Western University of Pennsylvania. Because of family considerations, however, he did not enter, but went to work for the Westinghouse Electric & Manufacturing Co., East Pittsburgh, where he spent about seven years in the operating and inspection departments.

During the years 1901–1903 Mr. Barnes was engaged in automobile work, first in charge of the electric garage of Banker Brothers Company, in Pittsburgh, then in the experimental and designing departments of the Pope Motor Car Company at its Waverly Plant, Indianapolis, Ind. He next designed, installed, and operated the electrical and mechanical equipment of the Launch & Gondola Concession Co. at the Louisiana Purchase Exposition at St. Louis, Mo., and also handled construction work for other concessions.

Following the exposition he was connected with the Peerless Motor Car Company for a time in its branch in New York, N.Y., after which he was located at Leadville, Colo., for several years, performing operating and maintenance work at the Yak Mill of the American Zinc Extraction Company, serving as superintendent of the electrostatic plant of the Lanyon Zinc Company, and engaging in the design, installation, and repair of mine and mill equipment.

In 1908 Mr. Barnes went to Denver, Colo., where he carried on business as a consulting electrical and mechanical engineer until his death on May 12, 1938. He specialized in labor-saving equipment and general power applications and pioneered in storage-battery applications to heavy haulage problems, such as haulage at the Big Five Mining Company, Idaho Springs, Colo. He designed many power installations for unusual conditions. He took a great interest in local construction works, whose progress he watched whenever he could. He contributed a number of articles on his work to the technical press.

Mr. Barnes became a member of the A.S.M.E. in 1920 and as a member of its Detroit Section served as chairman of the Hotels and Registration Committee for the 1934 Semi-Annual Meeting held in Denver. He also belonged to the American Institute of Electrical Engineers from 1919 to 1935 and had served as chairman of its Colorado Section and as alternate representative of the Institute on American Engineering Council. He was a member of the Technic Club, Denver, and of the Elks fraternal order.

Mr. Barnes married Marie Louise Warnecke, in Denver, in 1917, and was survived by her.

WILLIAM OLIVER BARNES (1864–1939)

William Oliver Barnes, consulting engineer, Worcester, Mass., died on September 8, 1939. He was born at Newburgh, N.Y., on May 16, 1864, son of David A. and Elsie E. (Ackerman) Barnes. His early education was secured in the public schools of Paterson, N.J., and he was graduated from Stevens Institute of Technology in 1884 with a mechanical engineering degree.

Following his graduation Mr. Barnes engaged in silk manufacture at Paterson under the firm name of Barnes and Reel for five years, then at Barmen, Germany, for two years, and again in Paterson until 1895, as superintendent of the Barnes Manufacturing Company. Then he followed the same line of work as superintendent of the Gregory Silk Manufacturing Company, Scranton, Pa., for a year.

Mr. Barnes turned to the design of tools and development of processes for the manufacture of typewriters, with the Blickensderfer Manufacturing Company, Stamford, Conn., in 1895, and continued there for five years. Subsequently he was engaged in design work on automobiles for the American Bicycle Company, Toledo, Ohio, then with the Mergenthaler Linotype Company, Brooklyn, N.Y., for a short time. From 1902 to 1908, he was connected with the Ross Rifle Company, of Hartford, Conn., the latter part of the time in charge of the company's factory at Quebec. In the following years he was, first, assistant superintendent of the Miller Lock Company, Philadelphia, Pa., then mechanical engineer at the Iver-Johnson Arms and Cycle Works, Fitchburg, Mass. During World War I he took an active part in machine tooling of one of the large ordnance plants in the eastern part of the United States. After the war he took up consulting practice in Leominster, Mass., later removing to Worcester and continuing until his death in development and inventive work in the machine tool and radio fields. He invented and manufactured the Barnes precision cutter grinder, which was widely used during the war both in the United States and abroad in arsenals and other manufacturing plants engaged in war work. Many other inventions had been patented by him.

Mr. Barnes married Grace D. Herdman in 1889. Her death, as well as that of their two children, William Oliver and Herdman Barnes, preceded his. A brother W. C. Barnes, of Chicago, survives him.

Mr. Barnes had been a member of the A.S.M.E. since 1908.

FREDERICK EMIL BAUSCH (1871–1938)

Frederick Emil Bausch, whose death occurred in St. Louis, Mo., on April 18, 1938, was born on January 8, 1871, at Mannheim on the Rhine, Germany. He came to the United States as a boy and prepared for college at the St. Louis High School. He was graduated from Washington University, St. Louis, with an E.E. degree in 1892 and an M.M.E. degree was conferred upon him by Cornell University four years later. He taught at the St. Louis Manual Training School during the years 1892–1895.

From 1896 to 1898 Mr. Bausch worked in the electrical laboratory of the Bell Telephone Company of Missouri, at St. Louis, and during the next two years was a draftsman in the Mechanical Department of the Missouri Edison Electric Company in that city. He was advanced to the position of assistant mechanical engineer in 1900, but soon afterward left to become chief engineer of the Pittsburgh Plate Glass Works at Crystal City, Mo. In 1901 he made another change, becoming western manager of The Hooven-Owens-Rentschler Company at St. Louis, the position which he occupied until 1930. In 1924 he also became owner of the Fred'k E. Bausch Fire Clay Mines. Since 1930 he had maintained his own office as sales engineer, in St. Louis.

Mr. Bausch was elected to membership in the A.S.M.E. in 1904. He was an active member of the St. Louis Section, which he served as secretary in 1913, chairman in 1914–1915, and member of the executive committee for the next two years. A brother, Adolph Bausch, of St. Louis, survives him.

PHILIP E. BLISS (1885–1939)

Philip E. Bliss, president of The Warner & Swasey Co., Cleveland, Ohio, died unexpectedly on April 11, 1939, after a brief hospitalization for treatment of a heart ailment. Surviving him are his widow, Loretta E. (Crane) Bliss, whom he married in 1904, and two children, Mary A. (Mrs. Edgar B. Gausby) and Charles William Bliss.

Mr. Bliss was born in Cleveland on December 14, 1885, son of

Julius E. and Arabel (Hauxhurst) Bliss. He attended the public schools in North Fairfield, Ohio, where his father was a well-to-do farmer, and had three years at Ohio Wesleyan University. Leaving there in 1904, he spent the next six years as a junior secretary in Y.M.C.A. work in Cleveland and New York. He returned to Cleveland in 1910 to enter the employ of The Warner & Swasey Co. as junior clerk in the accounting department. From that position he advanced to auditor, and later treasurer; in 1924 he was made a vice-president, and in 1928, president.

Quiet and self-effacing, Mr. Bliss was an outstanding leader among machine tool manufacturers. The depression years were particularly severe ones for this industry, but his courage never faltered, and his wise guidance not only brought his own company safely through, but also helped other organizations to weather the storm.

Mr. Bliss was tremendously interested in the welfare of his employees, and to help facilitate the solution of their problems he had the door to his private office removed so as to encourage them to seek discussion and friendly advice.

Mr. Bliss had numerous interests outside his immediate business activity. He was past-president (1927–1928) of the National Machine Tool Builders' Association, and had been serving as a member of the Executive Committee of the National Industrial Conference Board. He had a keen sense of civic duty, evidenced by serving several terms as a director of the Cleveland Chamber of Commerce; by being a Trustee of St. Luke's Hospital and Case School of Applied Science, a director of the Society for Savings, and vice-president of the Caxton Building Company, all of Cleveland.

Mr. Bliss belonged to numerous organizations and clubs. He became an associate of the A.S.M.E. in 1923, and served on its Committee on Education and Training for the Industries in 1935–1936. He was a member of the Board of Directors of the American Standards Association in 1937–1938. He also belonged to the Army Ordnance Association and the Cleveland Engineering Society, and was a member of Phi Delta Theta, the Union Club (Cleveland), and the Union League Club (New York).

ALBERT (HAMMOND) BUCKLER (1875–1939)

Albert (Hammond) Buckler, who died on December 1, 1939, was born on August 24, 1875, at Long Branch, N.J., son of Albert and Sarah A. (Hardover) Buckler. At the age of sixteen he became an apprentice machinist at the New York Navy Yard. During the period of his apprenticeship there he also took various engineering courses in evening classes at Pratt Institute. In later years he took courses at George Washington University and New York University. He was employed by the Navy Department until 1901, securing both machine shop and drafting room experience and spending some time at sea as an oiler in army transport service.

Early in 1901 Mr. Buckler took a position as engine draftsman with the William Cramp Ship & Engine Building Co. In the summer of 1903 he left that employment to become draftsman in the Turbine Department of the Westinghouse Machine Company, East Pittsburgh, Pa., where he spent about five years, part of the time as salesman for steam turbines and gas engines.

Mr. Buckler returned to government service in 1908 when he began a three-year period at the Naval Gun Factory, Washington, D.C., as draftsman and designer. Subsequently, from 1911 to 1919, he was in the U.S. Lighthouse Service, first as chief draftsman in the General Depot at New York, then from 1914 on as assistant superintendent of the Service. While in the Service he invented a boat for its use. He also taught marine engineering at Johns Hopkins University in 1917–1918.

During 1919–1920 Mr. Buckler was with the International Mercantile Marine Co., New York. While repair manager in the Construction Department, he was employed in connection with repairs on the S.S. *Leviathan*, and later, as assistant production engineer, he supervised the reconstruction of the twelve-story office building of the company at No. 1 Broadway, New York.

Mr. Buckler had been production engineer for Gibbs Brothers, Inc., and Gibbs & Cox, New York, since 1921. He installed production control and payment systems as applied to the construction and repair of ships, and engaged in estimating and design. He was intensely interested in everything pertaining to ships, the Navy, and related matters.

Mr. Buckler entered the A.S.M.E. as a junior member in 1905, became an associate-member in 1925, and was automatically transferred to the grade of member in 1935. He belonged to the Masonic fraternity. He is survived by his widow, Grace (Welch) Buckler, of Washington, D.C.

ELLWOOD BURDSALL (1856–1939)

Ellwood Burdsall, who died on March 10, 1939, after an illness of six months, had held membership in the A.S.M.E. since the year of its formation, having become a junior member in April, 1880. He was promoted to the grade of member in 1916. For many years he had been active in the technical committee work of the Society. He was a member of the Special Committee on Tolerances in Screw Thread Fits from the time of its formation in 1912 until it was discontinued in 1921. He continued his service in this field of standardization as a representative of the A.S.M.E. on the Sectional Committee on the Standardization and Unification of Screw Threads, organized in 1921, until the committee was reorganized in 1929. From its beginning in 1922, he was a member of the Sectional Committee on Bolt, Nut and Rivet Proportions and of its subcommittee on Wrench-Head Bolts and Nuts, and from 1924 until his death he was on its subcommittees on Round Unslotted Head Bolts and on Plow Bolts.

Mr. Burdsall was born on September 20, 1856, at Harrison, N.Y., a twin of Richard H. Burdsall, banker and industrialist. His parents were Ellwood and Hannah (Haviland) Burdsall. He attended the Friends Seminary in New York, N.Y., and Swarthmore College, and was graduated from Cornell University in 1878 with a B.M.E. degree.

Following his graduation he became draftsman for Russell, Burdsall & Ward, the bolt and nut company originally founded as the Union Screw Company in Port Chester, N.Y., in 1845 by his father, William E. Ward (a founder member of the A.S.M.E.), and Isaac D. Russell. Mr. Burdsall became secretary in 1880 and treasurer in 1915, and served in these offices until his death. The company was merged with the Port Chester Bolt & Nut Co. in 1901 to form the Russell, Burdsall & Ward Bolt and Nut Co.

He was also a member of the American Iron and Steel Institute. He was president of the First National Bank & Trust Co., of Port Chester, from 1915 until his death, and a former president of the Port Chester Savings Bank and local Board of Education. He was one of the founders of the Port Chester Rotary Club, a governor of the Old Port Chester Country Club, and a member of the Indian Harbor Yacht Club, and Red Spot Fishing Club, of Upton, Me. He was a devout Quaker and had been presiding officer of the New York Yearly Meeting.

Surviving him are two sons, Richard L. Burdsall and Robert L. Burdsall, both of Port Chester, N.Y. His wife, Luella T. (Morris) Burdsall, of Milton, Ind., whom he married in 1893, died in 1919. A third son, Dr. E. Morris Burdsall, died on April 21, 1939.

FRED JOSEPH CHATEL (1891–1939)

Fred Joseph Chatel, assistant engineer at the Delray Station of The Detroit Edison Company, died from a heart attack at his home in Detroit, Mich., on April 24, 1939.

Mr. Chatel was born at Kearsarge, Mich., on February 20, 1891, son of Joseph and Mary Louise (Doucette) Chatel. He prepared for college at the high school in Calumet, Mich., graduating in 1909, and received a B.M.E. degree from the University of Michigan in 1914. He had been connected with The Detroit Edison Company since then, except in 1917–1919, during World War I. Prior to the war he spent about six months in the Research Department, followed by something over two years as boiler room engineer at the Connors Creek plant. He returned to this position after the war for two years and a half, then was transferred to the Delray plant, where he held the title of technical engineer until 1929, when he was appointed assistant engineer. He contributed a paper on "Steam-Condenser Practice and Performance" to the 1927 Annual Meeting of the A.S.M.E., and was co-author with Paul W. Thompson of one on "Stoker Developments at the Detroit Edison Company's Delray Power House No. 3," presented at the 1932 Annual Meeting. These papers were published by the Society, the first in *Mechanical Engineering* for March, 1927, and the second in the Transactions, 1933. Mr. Chatel held a patent on a slag deflector for furnace walls.

During the war Mr. Chatel served in the navy, enlisting as a machinist's mate in April, 1917, and advancing to a lieutenant, junior grade, in the naval reserves. He was first chaplain of the Thomas A. Edison Post of the American Legion in 1931–1932 and senior vice-commander in 1937–1938.

Mr. Chatel was elected a member of the A.S.M.E. in 1938 and was a member of the Engineering Society of Detroit. He is survived by his widow, Genevieve M. (Doty) Chatel, whom he married in 1919, and by a daughter Elaine, and three sons, Paul F., John E., and Robert J. Chatel.

ERNEST LOWELL CLIFFORD (1883–1939)

Ernest Lowell Clifford, district sales manager of the Babcock & Wilcox Co. at Detroit, Mich., died on February 8, 1939.

Mr. Clifford became a member of the A.S.M.E. in 1914 and served on the Sectional Committee on the Safety Code for Conveyors and Conveying Machinery, representing the Associated General Contractors of America, from 1926 to 1936. He was also a member of this committee's Subcommittee No. 6 on Air, Steam, or Liquid Conveyors from 1927 to 1936. Other organizations to which Mr. Clifford belonged included the Western Society of Engineers, the Engineering Society of Detroit, Detroit Yacht Club, and masonic fraternity.

The son of Benjamin Franklin and Florence Lulu (Woollen) Clifford, Mr. Clifford was born in Indianapolis, Ind., on February 23, 1883. His early education was secured in public schools in Tacoma, Wash., and Chicago, Ill., and he was graduated from the Massachusetts Institute of Technology with a B.S. degree in 1904. Following his graduation he spent a year and a half as assistant to Prof. S. H. Woodbridge, of the M.I.T. faculty, in his private practice, chiefly heating and ventilation, in Boston, Mass., and Washington, D.C.

At the end of 1905 Mr. Clifford began work as draftsman for Pierce, Richardson & Neiler, mechanical and electrical consulting engineers, in Chicago. He was employed in that city and vicinity for about seventeen years. After leaving his first position in the spring of 1907, he spent about a year with the L. H. Prentice Co., heating and ventilating contractors, then for a short time was inspector for the village of Wilmette in connection with sewer construction. Next he was inspector of construction and assistant to the chief construction engineer, C. G. Y. King (Mem. A.S.M.E.), of the Cosmopolitan Electric Company, in the construction of the Grove Street Power Station. He was in charge of construction and engaged in power station engineering for Sargent & Lundy from early 1910 to the middle of 1913, then worked on designs and estimates for W. A. Pope, Chicago contractor, for a few months. Following this he was designer and construction superintendent for the Mead-Morrison Manufacturing Company, then became assistant chief engineer of the Cannon-Swenson Company, contractors for chemical and sugar plants. He later became a partner in this organization, and its vice-president.

From the fall of 1922 until April, 1927, Mr. Clifford was connected with McClellan & Junkersfeld, Inc., of New York, working on the design and construction of power stations and industrial plants. The Cahokia Power Station, at St. Louis, Mo., was one of the plants built under his direction. He began work for the Babcock & Wilcox Co. in 1932. He was in charge of the Detroit office from then until 1936, during which time it was part of the Chicago sales territory, operating under the Chicago district sales manager. In 1936 he was made district sales manager of the Detroit territory, reporting direct to the general offices in New York.

Mr. Clifford married Muriel Ruby King, a native of Liverpool, England, in 1907, who survives him, together with their three children, Margaret King, Jane Wingate King, and Franklin King Clifford.

DAVID BANKS CLOUDSLEY (1876–1934)

David Banks Cloudsley was born on December 16, 1876, at Toronto, Ont., Canada. He attended schools in that city and at Williamsport, Pa., where in 1892–1893 he served an apprenticeship with the Williamsport Engineering Supply Company, working on the manufacture of brass goods.

In 1894 Mr. Cloudsley went to Buffalo, N.Y., and after a short time in the drafting room of the Buffalo Forge Company he secured employment with the Buffalo General Electric Company as machinist and assistant engineer. He spent four years in this position, then in 1899 engaged in the design and construction of copper smelting furnaces with O. S. Garretson, of Buffalo.

During the years 1900–1901 he was employed by the Frontier Engine Works, Buffalo, as designer of gas and steam engines and special machinery. The following year he was working on traction engine design for the Buffalo Pitts Company.

In 1903 Mr. Cloudsley entered upon a long period of work for the City of Buffalo. At first he was in the Bureau of Engineering, designing a sewage pumping plant. Then he was transferred to the Bureau of Water, assigned to the design and installation of a boiler plant. Subsequently, as assistant to the chief engineer, he designed and superintended the installation of a new pumping station, of which he later became chief engineer. He served in this capacity until 1916. Two years later he became associated with the Zaremba Company, of Buffalo, as a design engineer, and he was employed by that organization until his death from a ruptured appendix on March 17, 1934.

Mr. Cloudsley became an associate of the A.S.M.E. in 1908. A brother, Arthur P. Cloudsley, of Buffalo, survived him.—[Biography compiled from best obtainable information, not all of which could be verified.]

WILLIAM LAWSON CONRAD (1873–1939)

William Lawson Conrad, a member of the A.S.M.E. since 1917 and active in the work of the Society's Textile Division, died at the Sibley Memorial Hospital, Washington, D.C., on November 29, 1939, from pneumonia. He is survived by his widow, Frances A. (Cushing) Conrad, whom he married in 1906.

Colonel Conrad was born at Topsfield, Mass., on September 17, 1873, son of Thomas Joshua and Margaret Agnes (O'Connor) Conrad. He attended school in Concord and Fitchburg, Mass., and after graduation from high school served an apprenticeship at the Fitchburg Machine Works. The record of his early experience, as taken from his application for membership in the A.S.M.E., lists the following: foreman, Putnam Machine Company, Fitchburg; assistant to assistant superintendent, United Shoe Machinery Company, Albany Street plant; and master mechanic, Sayles Bleacheries, Saylesville, R.I.

For many years Colonel Conrad was associated with Henry Laurence Gantt. According to the biography of Mr. Gantt, written by Leon P. Alford, the first contact was while Conrad was still a high school boy and was employed by Gantt during the organization of the Simonds Rolling Machine Company. Dr. Alford also lists Mr. Conrad as one of those trained in Gantt's methods at the Sayles Bleacheries. These early contacts grew into a close association which continued until Gantt's death in 1919. As a member of Gantt's organization, Colonel Conrad had part in many installations of modern methods of management in industrial organizations, and after the death of Mr. Gantt he continued in active practice as a consultant in production and management methods until his retirement in April, 1933. He had resided in Washington since then.

Another important part of his life was his military service. This was reported in detail in the January-February, 1940, issue of *The Quartermaster Review*, from which the following is taken:

"Colonel Conrad's first Army service came when, as a young man, he joined Company D, of the 6th regiment, National Guard, and was sent to Puerto Rico for service in the Spanish-American War. His next war service came on November 15, 1917, when he was mustered back into federal service as major, Q.M.C., N.G. (U.S., Mass.), and assigned to duty as camp quartermaster and sub depot quartermaster, Beauregard, La.

"In October, 1918, Colonel Conrad was assigned to duty as coast defense quartermaster and disbursing officer at Sandy Hook, N.J., where he served until September 26, 1919, when he was sent to Camp Alfred Vail as camp supply officer to stay until his discharge on October 31, 1919.

"On December 22, 1919, Colonel Conrad was appointed a lieutenant-colonel in the Quartermaster Reserve and on June 2, 1923, was promoted to colonel, Quartermaster Reserve. He was transferred to the Inactive Reserve on September 18, 1937, upon reaching retirement age.

"Colonel Conrad was a charter member of the Fitchburg Post, No. 10, American Legion, and of the Guanica Camp, U.S.W.V. He was also a member of the Massachusetts Commandery of the naval and military order of the Spanish-American War. He was the first Quartermaster Reserve officer to be elected national president of the Quartermaster Association and his best efforts went into fulfilling the responsibilities of that high office."

Colonel Conrad was on the Executive Committee of the A.S.M.E. Textile Division as its secretary from 1927 to 1930, as chairman in 1934, member in 1935, and associate from then until his death. He belonged to the Elks fraternal order and the Knights of Columbus and for a time was an advisor for the Nichols Junior College, Dudley, Mass.

L D CRAIN (1868–1942)

L D Crain, professor emeritus of mechanical engineering at Colorado State College, died unexpectedly at Long Beach, Calif., on March 15, 1942. Professor Crain had been in fairly good health and quietly passed into his last sleep while Mrs. Crain was reading to him. The A.S.M.E., and especially the Colorado Section, mourns the passing of one who has been very active in the Society affairs and who has played an important part in the success of the Colorado Section.

Professor Crain was born in Angola, Ind., on February 3, 1868, son of Abram and Hariet (Perry) Crain. He attended the local district school and the high school at Angola. After finishing high school he entered Purdue University, where he received the degree of Bachelor of Mechanical Engineering in 1892. Later he went to Cornell University and received the degree of M.M.E. in 1902.

He became assistant professor of mechanical engineering at Colorado State College in 1892. In 1903 he organized the Department of Electrical Engineering at that institution and became the first professor of electrical engineering at Colorado State College. From 1905 to 1912 he engaged in contracting and engineering work in Fort Collins, returning to the college in 1912 as associate professor of mechanical engineering. In 1917 he was appointed professor and head of the Mechanical Engineering Department, which position he held until his retirement in 1936.

Professor Crain became a junior member of the A.S.M.E. in 1895 and advanced to member in 1904. He relinquished his membership during the year 1906–1913, and was reinstated with the grade of member in 1914. He was a member of the Colorado Executive Committee from the time of its organization in 1919 until his death and was chairman of the Section from 1921 to 1923. At the time of his death Professor Crain was Section historian and was actively engaged in compiling a complete history of the A.S.M.E. in Colorado. He served on the Regular Nominating Committee of the Society in 1934.

He was a member of Sigma Xi, Phi Kappa Phi, Sigma Tau, and Rotary International. Because of his interest in civic affairs his fellow citizens elected him to various offices, including that of secretary of the Park Commission and president of the Chamber of Commerce of Fort Collins.

He was a 33rd degree Mason and Past Grand Master, A.F. & A.M., of Colorado. In 1928 he was appointed a trustee of the Colorado Masons Benevolent Fund Association and in 1934 he became the state chairman of the George Washington Masonic National Memorial Association.

In addition to his widow, Aureli (Bouton) Crain, whom he married in 1901, Professor Crain is survived by three sons, L D Crain, Jr., Richard W. Crain, and Clark Nixon Crain.

Professor Crain will long be remembered by his former students and associates as a man of splendid character and one who was always interested in the welfare of others.—[Biography prepared by J. T. STRATE, Ft. Collins, Colo. Mem. A.S.M.E.]

JOHN RORISON DOUGLAS (1883–1938)

John Rorison Douglas, chief construction engineer of Courtaulds, Ltd., Coventry, England, died on April 4, 1938, while on duty at the Preston Works branch of the company. He had been a member of the A.S.M.E. since 1931.

Mr. Douglas was born at Perth, Scotland, on August 1, 1883. He attended the Perth Academy and the Technical Section of Dundee University College. He served an apprenticeship with the Lily Bank Shipbuilding & Engineering Co., Dundee, from 1899 to 1903, and with Chas. Parker & Sons Ltd., Scotland, during the next three years. He was then employed by the J. M. Davidson Construction Co., Johannesburg, South Africa, and in 1908 became its chief engineer. In 1908–1909 he was engaged in the erection of a plant and equipment for the East Rand Gold Mines, and other construction work. He took a position as chief engineer for the Victory Hill Gold Mines, Barberton, Transvaal, in 1910, where he continued for about two years.

In 1912 Mr. Douglas designed and erected a complete textile plant at Odessa, Russia, and the following year, silk textile mills at Lyon, France. During the early part of 1914 he was chief engineer and manager of the New Port (Monmouthshire) Ship Repairing Co., repairing ocean-going ships. At the outbreak of World War I he joined the British navy as an aviator and during the most of the war served in that capacity. In 1917 he directed the raising of the S.S. *Kassandna* from the bed of the Mediterranean.

After the War he was engaged for a short time in the design and erection of an oil plant for extracting oil from peanuts and cereals for margarine manufacture. He joined the Courtaulds staff in 1921 and during the remainder of his life directed the design and erection of textile plants, many of them for the manufacture of rayon goods, in England, Germany, Canada, and other countries.

Surviving Mr. Douglas are Mrs. E. Douglas, of Coventry, and two sons. The elder, H. W. Douglas, is assistant plant manager of Courtaulds (Canada) Limited, Cornwall, Ont., Can., and the younger, A. J. Douglas, is a member of the engineering staff of the Bristol Aircraft Co. Ltd., Bristol, England.

OSWALD DUDA (1875–1938)

Oswald Duda, who had recently resigned as chief engineer for the American Well & Prospecting Co., Corsicana, Texas, died on June 2, 1938, of a heart attack. He had planned to go into business in partnership with his son.

A native of Austria, Mr. Duda came to the United States in August, 1907, and became a naturalized citizen at Houston, Texas, in 1912. He was born in Trzynietz, Silesia, on June 7, 1875. He secured his early technical education in the industrial school in Trzynietz and later took a course in mining and metallurgy in Leoben, Styria. From 1889 to 1893 he served an apprenticeship in the machine, metal spinning, and forging trades with the Erzherzog Albrecht Corporation, Silesia. He then worked on production estimating at the Union Blech Werke, Zolyom, Hungary, and, for six months, obtained foundry practice at the K.O.R.R. Works, Ruttka, Hungary. During the years 1898–1900 he took his course in the mining and metallurgical college at Leoben, then worked for a year for the Russian Shipbuilding Corporation, Nikolajeff, Russia, as a designer. From 1901 to 1907 he did similar work for the Rothschilds Werke, Witkowitz, Austria.

Mr. Duda's first position in this country was as a designer for the Union Iron Works, Houston, where he was engaged from 1907 to 1913. This employment was followed by similar work in 1914–1915 for the Calhoun Pattern & Foundry Co., and in 1915–1919 for the Houston Car Wheel & Machine Co., both of Houston. In 1919 he became chief mechanical engineer for the Reed Roller Bit Company, Houston. He remained with this company until 1930, when he was engaged as chief engineer of the American Well & Prospecting Co., in charge of designing and supervising the manufacture of oil well drilling machinery.

A number of patents had been taken out by him and copatentees and assigned in most cases to the last two companies for which he worked. These were on wrenches, deep-well-drilling apparatus, bits and reamers, and valve mechanisms.

Mr. Duda had been a member of the A.S.M.E. since 1927. He was a 32nd degree Mason and a Shriner, belonging to the Arabia Shrine Temple in Houston from 1927 until his death. He served as secretary of the Order of the Eastern Star in 1929–1930. He is survived by his widow, Emmanuela (Roszmetalsky) Duda, whom he married in 1904, his son, Erwin G. Duda, of San Antonio, Texas, and a daughter, Mrs. Inez (Duda) Schroeder.

CARL ERIC EKLIND (1878–1938)

Carl Eric Eklind, son of Carl Edward and Josephine (Conti) Eklind, was born in Orebro, Sweden, on October 8, 1878. He was educated in Sweden (with some postgraduate studies in Germany) and performed a year of required military service in the Swedish army, during which he received a rifle from the King as first prize in a marksmanship contest.

His first recorded work, after his graduation in 1900 from the University of Orebro as a mechanical engineer and chemist, was with the Pressed Steel Car Company, McKees Rocks, Pa., in 1903–1904. He then entered the employ of the Chicago, Topeka & Santa Fe Railway Co., Chicago, Ill, where he advanced from draftsman and checker on passenger and freight equipment to chief draftsman of the Car Construction Department. He became thoroughly familiar with every phase of car construction.

From 1924 until his death on December 1, 1938, he was associated with the Camel Company and Camel Sales Company of Chicago (dealers in railway specialties and supplies, taken over by the Youngstown Steel Door Company in 1935). He became assistant to the vice-president of the Camel Company in 1930 and at the time of his death was serving as vice-president of the Camel Sales Company.

Mr. Eklind had been a member of the A.S.M.E. since 1919. He belonged to the Illinois Athletic Club, Chicago, and the Acacia Golf Club. He married Ella Verdia Neun, of Pittsburgh, in 1908, and is survived by her and two children, Robert Warren Eklind, a lieutenant in the U.S. Army, and Marjorie V. Eklind, residing with her mother in Berwyn, Ill.

EDGAR CONWAY FELTON (1858–1937)

Edgar Conway Felton, a member of the A.S M.E. since 1885 and a manager of the Society for the term 1898–1901, was born at Thurlow (now Chester), Pa., on April 13, 1858, the son of Samuel Morse and Maria Low (Lippitt) Felton, and died at Haverford, Pa., on September 18, 1937.

He was prepared for college by Reginald Heber Chase, in Philadelphia, Pa., entered Harvard College, where he was graduated in 1879 with the degree of Bachelor of Arts.

He then spent one year in travel in Europe, returning in 1880 to begin work in the chemical laboratory of the Pennsylvania Steel Company at Steelton, Pa. The following year he was a laborer in the rolling-mill of the Sanderson Steel Company at Syracuse, N.Y., but he returned in 1883 to Steelton to take the position of mill superintendent. He rose rapidly through the grades of assistant superintendent and superintendent of works (1884–1893) and general

manager (1893–1896), and was elected president in 1896, serving until 1916, when the company was merged with the Bethlehem Steel Corporation, and he retired from active business. Under his management the departments of bridge building and shipbuilding were greatly enlarged.

While living at Steelton he was interested in the development of electric railways in that vicinity, and on the formation of the Harrisburg Traction Company was chosen its president.

During the World War he served as director of civilian service and labor, a department of the Pennsylvania Committee of Public Safety, and as examiner of the Shipbuilding Labor Adjustment Board for the Philadelphia District.

He was manager of the Gerard Trust Company and the Western Savings Fund Society, a director of the Pennsylvania Railroad, the General Asphalt Company, the DeLong Hook & Eye Co., and the Philadelphia & Western Railway Co., and a trustee of Drexel Institute, and he had served as president of the board of directors of the Steelton and the Haverford township schools. He had also served as secretary and treasurer of the Steelton Public Library.

Among the many other societies of which he had been a member were The Franklin Institute, the American Institute of Mining and Metallurgical Engineers, and the American Iron and Steel Institute (director).

He was also a member of the Harvard Club of Philadelphia (president), the University Club of Philadelphia (vice-president), the Philadelphia Club, and the Merion Cricket Club (governor).

To Harvard College he gave much of his time and interest, and he served as an overseer from 1914 to 1920 and from 1921 to 1927.

Fond of travel, he made several trips to Europe and visited Cuba and Jamaica. In 1911 he attended the conference of steel manufacturers of the world at Brussels, Belgium, and he made an automobile tour of France, England, and Wales.

In 1884 he married Alice Bent, daughter of Winslow Brigham and Jane Elizabeth (Tomlinson) Bent, of Ann Arbor, Mich., and Chicago, Ill., who survives him, together with six children, Mrs. Emmett Robinson Tatnall (Margaret Felton) of Haverford, Mrs. Sumner Rulon-Miller (Eleanor Felton) of Ardmore, Pa., Samuel Morse Felton, 3rd, of Boston, Mass., Cornelius Conway Felton of New York, N.Y., Edgar Conway Felton of Haverford, and Winslow Bent Felton, of Boston.—[Biography adapted from a memoir published in The New England Historical and Genealogical Register, January, 1938.]

FREDERICK CROMWELL FIELD (1875–1937)

Frederick Cromwell Field, who died at the Germantown Hospital, Philadelphia, Pa., on September 22, 1937, was born in Brooklyn, N.Y., on October 17, 1875, son of Richard Cromwell and Mary (Manning) Field. He attended the Friends School and Polytechnic Institute, in Brooklyn, then entered the Massachusetts Institute of Technology, where he studied for six years, taking both the electrical and mechanical engineering courses.

His first position, in 1898, was with the Edison Electric Illuminating Company of Brooklyn, in connection with switchboard operation. After a year there he was employed by the N.J. Foundry & Machine Co., New York, on estimating for engineering contracts; then in 1900–1901 was a member of the firm of Field and Everett, consulting engineers, New York. Subsequently he was engaged in estimating, designing, and construction work for Westinghouse, Church, Kerr & Co., New York; helped to establish and served as treasurer of the Engineer Company, which handled mechanical draft installations; was engineer of the building department of the N.Y. Telephone Co.; served as consulting engineer with Wendell and MacDuffie, New York; and did reporting and estimating for J.G. White & Co., Inc., New York, and E. I. du Pont de Nemours & Co., Wilmington, Del.

In 1911 Mr. Field became president and general manager of the Standard Arms Manufacturing Company, of Wilmington, and he continued with that organization until 1917. He was commissioned a captain in the Ordnance Reserve Corps in August, 1917, and assigned to active duty with the Remington Arms Company of Delaware, at Eddystone, Pa., as inspector in the Small Arms Division. He was promoted to the grade of major in the regular army in February, 1918, and in May of that year was transferred to the Inspection Division at Washington. He was again transferred, the following November, to the Philadelphia Ordnance District Office, in charge of the Tank, Tractor, and Trailer Division. He was honorably discharged from service on July 1, 1919.

Except for some consulting work in Philadelphia, Mr. Field had no professional business connections during the remainder of his life. In addition to his membership in the A.S.M.E., to the member grade of which he was elected in 1916, he belonged to the Engineers Club of Philadelphia, Crescent Club (Brooklyn), and Phi Beta Epsilon fraternity.

Surviving Mr. Field are his widow, Florence A. Field, two daughters, Mrs. C. F. Bond and Doris Field, and two sons, Harold A. and Frederick C. Field, Jr., all of Philadelphia at the time of his death.

CHARLES HARDY HARRIS (1878–1938)

Charles Hardy Harris, general engineer of the Virginia Electric & Power Co., Richmond, Va., an affiliate of the Stone & Webster Engineering Corp., of Boston, Mass., died at his home in Richmond on October 22, 1938. Although he had been in poor health for about a year, his illness was not regarded as serious until shortly before his death.

Mr. Harris was born in Natick, Mass., on September 3, 1878, the son of Charles O. and Alice D. (Osgood) Harris. He attended the Natick schools and was graduated from the Massachusetts Institute of Technology in 1901 with an S.B. degree in electrical engineering. He immediately entered the employ of the Stone & Webster Engineering Corp., at Boston, as an engineer-student. After a year he was transferred to Seattle, Wash., in the same capacity, completing his training with the Seattle Electric Company. During the remainder of his life he was assigned to service with different affiliated companies of the corporation. He was electrical and mechanical engineer of the Minneapolis (Minn.) General Electric Company, 1905–1912, superintendent of construction of the "Goat Rock" power development at Columbus, Ga., the following year, and subsequently was connected with the Mississippi River Power Company at Keokuk, Iowa, Western United Gas & Electric Co., Aurora, Ill., and Tampa (Fla.) Electric Company, before taking up his duties in Richmond in 1927.

Mr. Harris had been a member of the A.S.M.E. since 1921 and was a member of the executive committee of the Virginia Section in 1936–1937. He also belonged to the American Institute of Electrical Engineers, Central Virginia Engineering Society, Hermitage Country Club, and the masonic fraternity. His wife Elinor (Condon) Harris, whom he married in 1905, died on July 25, 1940. Two brothers, Dr. Leslie W. Harris, of Natick, Mass., and Dr. Lucien H. Harris, of Northampton, Mass., survive him.

DANIEL AUGUST HEIKEL (1859–1925)

Daniel August Heikel was born at Ny Karleby, Finland, on October 20, 1859, and died in his native country on April 29, 1925. A considerable part of his life, beginning in 1882, was spent in the United States, and he had been a member of the A.S.M.E. since 1899.

Mr. Heikel was educated in Finland, and received a degree in mechanical engineering in 1880 from the Polytechnical Institute of Finland. After about two years in drafting work in St. Petersburg, Russia, he emigrated to this country, where he secured work in August, 1882, with the Chicago, Milwaukee & St. Paul Ry., in Milwaukee, Wis. Subsequently he was employed by Crane Brothers Manufacturing Company, Chicago, Ill., Iowa Iron Works Company, Dubuque, Iowa, and Kansas City Bridge & Iron Co., Kansas City, Mo., all in drafting. For four years, 1887–1891, he was superintendent of the Engine Department of Hoffman & Billings Manufacturing Co., Milwaukee, then spent about five and one-half years with the Nordberg Manufacturing Company, of that city, as sales agent and engineer.

Mr. Heikel was next chief engineer and partner with C. H. Bradley, Jr. & Co., of Pittsburgh, Pa., consulting and contracting engineers. Later he carried on an independent consulting practice in Pittsburgh until his return in 1902 to Finland, where he continued his work as a consulting engineer and contractor. He came to the United States again for a period of about six years, 1905–1911, the most of which time he was employed by the Nordberg Manufacturing Company in Milwaukee and as its representative in Pittsburgh. Since 1911 he had resided in Åbo, Finland. His widow, Berta Heikel, survived him.

THOMAS HIBBARD (1854–1938)

Thomas Hibbard, of Milton, Mass., whose death occurred on October 4, 1938, was born on February 16, 1854, in East Boston, Mass., the son of William Charlton and Sarah Ann (Smith) Hibbard. He was graduated from the Massachusetts Institute of Technology in 1875 with an S.B. degree in mechanical engineering and for the next five years was draftsman at the Atlantic Works, East Boston, on the general designing of engines and boilers, principally for marine service. Then he was employed, first as designer and later as assistant superintendent, by the Boston Sugar Refining Company, rebuilding its plant. Upon the completion of this work he set up his

own office for general mechanical engineering practice in Boston, but gave it up after several years to become chief draftsman for the Deane Steam Pump Company, Holyoke, Mass. He remained with this company until about 1890, when he was made treasurer and mechanical engineer of the George Lawley & Son Corp., South Boston, builders of yachts of all kinds. Here he designed and equipped the plant for building steel hulls, and had charge of the design and installation of motive power in steam and motor vessels built by the company. He also was responsible for all the financial matters of the company, as treasurer. He retired in 1918 at his own request, but continued to hold an interest in the corporation, and in 1927 he returned to serve as president and director for three years.

Mr. Hibbard became a member of the A.S.M.E. in 1889. He was also a member of the American Society of Naval Engineers and of the Technology Club. He was twice married. His first wife, Jennie M. Blackinton, whom he married in 1880, died in 1889. He remarried in 1899, his second wife being Bertha Bartlett, who died in 1941. Two children by each marriage survive them.

ROBERT HATFIELD IRONS (1876–1939)

Robert Hatfield Irons, president of the Central Iron & Steel Co., Harrisburg, Pa., died of toxic poisoning in the International Hospital at Naples, Italy, on January 5, 1939. He was not well when he and Mrs. Irons left New York early in December for a two-month cruise to Italy, Egypt, and the Holy Land, and was obliged to go to the hospital the day after their arrival in Naples.

Mr. Irons had been president of the Central Iron & Steel Co. since 1916. He entered the employ of the company in 1892, at the age of sixteen, and after serving as mill superintendent from 1899 to 1912, was appointed general superintendent and chief engineer. Since his election to the presidency of the company four years later he had also served as a director and member of the executive committee.

The son of George D. and Rebecca (Hatfield) Irons, he was born at Halifax, north of Harrisburg, on August 7, 1876. Supplementary to his early public and private schooling, he attended the Wilkes-Barre Academy and studied engineering under a tutor.

Mr. Irons became a member of the A.S.M.E. in 1922. He was a member of the Executive Committee of the Susquehanna Section of the Society from 1927 to 1930, serving as chairman in 1929–1930. He represented the Society on the Sectional Committee on Standardization of Plain and Lock Washers, and on its Subcommittee No. 1 on Plain Washers, from 1927 to 1931.

Mr. Irons was past-president of the Association of American Steel Manufacturers. He was also a member of the American Iron and Steel Institute, (British) Iron and Steel Institute, American Institute of Mining and Metallurgical Engineers, American Society for Metals, American Society for Testing Materials, Engineers' Society of Western Pennsylvania, The Franklin Institute, India House (New York), the Harrisburg Club, and numerous civic organizations in Harrisburg. He was a member of the executive committee of the National Planning Committee for the Harrisburg area and long had been identified with the welfare federation which provides funds for local charities.

Mrs. Irons was the former Miss Nellie Brandt, of Harrisburg.

L(LYWELLYN) HOWARD (HARDING) JENKS (1862–1939)

L. Howard Jenks, Sr., a member of the A.S.M.E. since 1891 and active in the technical committee work of the Society for some years, died suddenly on November 15, 1939, in Wheeling, West Va., while returning home from a long western trip. Mr. Jenks represented the American Society of Refrigerating Engineers, of which he was president in 1926, on the Sectional Committee on Standardization of Pipe Flanges and Fittings from 1921 to 1938, and from 1924 to 1938 was a member of two of its subcommittees, No. 1 on Cast Iron Flanges and Flanged Fittings and No. 2 on Screwed Fittings. A charter member of the A.S.R.E., he gave valuable service to that organization in its formative years and continued active in its affairs until his death. Other groups to which he belonged included the National Association of Practical Refrigerating Engineers, the Pennsylvania Society of New York, and the masonic fraternity.

The son of Col. Barton H. Jenks and Elesa (Saurwen) Jenks, he was born on October 25, 1862, at Holly Hall, the Colonial homestead of the Jenks family on the Delaware River near Bridesburg, now a part of Philadelphia. After completing his early education in public and private schools he took a course in mechanical drawing at The Franklin Institute. Securing a competitive free scholarship, he entered the University of Pennsylvania in 1880 and acquired his B.S. degree four years later. A year of postgraduate work brought him a C.E. degree in 1885.

Mr. Jenks worked with his father on the development of a power multiple coal drill and other patents during the first year after his graduation, then was associated with J. J. de Kinder (Mem. A.S.M.E.), general superintendent of the Philadelphia Water Department, in water works construction, for two years. From 1888 to 1896 he was connected first with the Consolidated Ice Machine Company, of Chicago, Ill., in its New York branch, in sales and tests of refrigerating machinery, and later with the Hercules Ice Machine Company, of Aurora, Ill., as its general Eastern representative, with headquarters in New York. Subsequently, for two years he was general manager of the R.B.S. & C. Electric Light & Power Co., of Rutherford, N.J.

In 1898 Mr. Jenks became manager of the Philadelphia office of the Frick Company, of Waynesboro, Pa. Later he was appointed manager of the Eastern District of the company, with headquarters in New York, where he continued until his retirement in 1930. He had been granted several patents on refrigerating equipment, including one on a safety inverted compressor valve. He planned and executed the first fish-freezing system in the Orient, including transportation by rail and the equipment of a fleet of refrigerated vessels.

Mr. Jenks married Emma B. Loag, of Philadelphia, in 1890. Her death occurred in 1930. Surviving them are a daughter, Marjorie F. Jenks, and two sons, L. H. Jenks, Jr., and Barton L. Jenks, all of Rutherford, N.J., where the family had long resided.

FORREST ROBERT JONES (1861–1936)

Forrest Robert Jones, a member of the A.S.M.E. since 1890, died on March 27, 1936, in Bolivar, Texas, where he had lived with his daughter for a number of years.

The early part of his life was spent in Ohio. He was born at Sharon on December 12, 1861, son of Martin Ryan and Susan (Hageman) Jones. He attended public schools in Sharon and in 1888 was graduated from Cornell University with a degree in mechanical engineering. He had served an apprenticeship at the Niles Tool Works, Hamilton, Ohio, prior to entering college.

From Cornell, Mr. Jones went to Orange, N.J., where he worked in the laboratory and phonograph works of Thomas A. Edison. He was sent to Kearney, Neb., to take charge of electric railway and lighting plant construction and served in 1890–1891 as superintendent of the mechanical department of the Edison General Company.

In the fall of 1891, Mr. Jones became instructor in mechanic arts at the University of Tennessee, Knoxville. He transferred to the University of Wisconsin, Madison, in 1893 and taught machine design there until 1899. He then became professor of drawing and machine design at the Worcester Polytechnic Institute, Worcester, Mass. In 1902–1903 he visited the principal technical schools and many commercial manufacturing plants in England and on the Continent to study teaching methods and manufacturing developments, giving special attention to gas and oil engines and gas producers for power purposes. Upon his return he taught machine design at Sibley College, Cornell University, for two years, then spent an equal period as professor at the Manhattan Automobile School, New York. From 1908 to 1920 he was located in Knoxville, Tenn., except for the years 1915–1916 and for three weeks in January, 1918, when he was again on the faculty of the University of Wisconsin. From 1920 to 1925 he was located in New York, N.Y.

Mr. Jones was the author of a number of books, including his "Automobile Catechism" and "Electric Ignition for Combustion Motors," and also contributed papers to technical societies and periodicals. He had been a member of the Society for the Promotion of Engineering Education and belonged to the Sigma Xi fraternity. He is survived by his widow, formerly Miss Johnnie House Fletcher, of Knoxville, whom he married in 1892, and by his daughter, Mrs. David McAnulty, a resident of Union City, Tenn., after her father's death.—[Biography compiled from best obtainable information, not all of which could be verified.]

WILLIAM HARRISON KAVANAUGH (1873–1939)

William Harrison Kavanaugh, professor of experimental engineering at the Towne Scientific School of the University of Pennsylvania since 1916, died on May 6, 1939, at the Abington Memorial Hospital, Philadelphia, Pa., after a brief illness. Prior to his connection with the Towne school he was a member of the faculty of the University of Minnesota for fifteen years. In both cases he was in charge of the experimental laboratory.

During these years Professor Kavanaugh was also engaged by various organizations as a consultant or to conduct special investigations and tests of equipment. A number of these assignments were for city and state commissions. He was frequently called upon as an engineering expert in litigation over patents and he was a member of the International Jury of Awards of both the Panama-Pacific Ex-

position, at San Francisco, Calif., in 1915, and the Sesquicentennial Exposition at Philadelphia in 1926. He was director of the courses for training automobile mechanics at the Junior Plattsburg Camp, Plattsburg, N.Y., in 1918.

Professor Kavanaugh was born at Williamsport, Pa., on August 19, 1873, son of Daniel and Emma (Ramsey) Kavanaugh. Following his graduation from the local high school he entered Lehigh University, where he received an M.E. degree in 1894. He was principal of the Miners and Mechanics Institute at Freeland, Pa., the next year, but resigned to go into the mercantile business in Williamsport. In 1897 he re-entered the teaching field as instructor in mechanical engineering at the University of Illinois. After a year there he was employed by the Pennsylvania Railroad Company, becoming chief draftsman in the office of the superintendent of motive power. He continued in that position until he took up his duties at the University of Minnesota in 1901.

Much of Professor Kavanaugh's varied experience was recorded by him in technical papers and reports, only part of which has been published. He also found time for extensive service in the engineering societies to which he belonged—the A.S.M.E., of which he became a junior member in 1902 and a member in 1910, the Society for the Promotion of Engineering Education, and The Franklin Institute. While at the University of Minnesota he held various offices in the A.S.M.E. Minnesota Section and served as its chairman in 1915. When he went to Philadelphia he became affiliated with the Local Section there and served it in a number of capacities, including that of chairman in 1923–1924. He took part in the national work of the Society as a member of the Regular Nominating Committee in 1923, of the Standing Committee on Relations with Colleges from 1924 to 1927 (chairman in 1927), of the Standing Committee on Constitution and By-Laws, 1934–1938 (chairman in 1938), and of technical committees as follows: Power Test Codes Individual Committee No. 1 on General Instructions, chairman from the time of its formation in 1918 until his death; Standing Committee on Standardization, 1920–1923; and Special Research Subcommittee on Stresses Due to Vibration of Shafting, 1921–1925. His service to other societies included membership on the S.P.E.E. Council.

Surviving Professor Kavanaugh are his widow, the former Julia Sara Vogt of Allentown, Pa., whom he married in 1896; a son, Dr. William Ramsey Kavanaugh, of Kalamazoo, Mich., and a daughter, Emma Cosette (Mrs. William H. Regelman), of Hatboro, Pa.

FRED KEY (1869–1939)

Fred Key, whose death occurred on February 25, 1939, was born in Auburn, Ky., on January 19, 1869. At the age of seventeen he entered upon an apprenticeship with the Louisville & Nashville R.R. After the completion of four years' training in Nashville, Tenn., he was transferred to Louisville, Ky., where he worked for the railroad for four years as machinist and draftsman.

From 1894 to 1898 Mr. Key was chief engineer of the Kentucky Heating Company, Louisville, then spent two years with the Southern Division of the Illinois Central Railroad at Jackson, Tenn., as engineer on roadway maintenance and other work. After that he was for sixteen years connected with the Boiler and Flywheel Department of the Fidelity & Casualty Co., in Kansas City and St. Louis, Mo. In 1916 he became vice-president and general manager of the Key Boiler Equipment Company, St. Louis, and he continued with this company (which in 1935 became the Key Company, East St. Louis, Ill.), until his death. He was also for some years vice-president and general manager of the St. Louis Pressed Steel Company, which was taken over by the Key Boiler Equipment Company in 1925. He had invented and patented numerous devices for use in power plants and oil refineries, including a one-piece hand-hold cap for watertube boilers and return-bend fittings for oil refinery heating coils.

Mr. Key had been a member of the A.S.M.E. since 1918. He also belonged to the American Petroleum Institute, National Association of Power Engineers, and the masonic fraternity. The University of Tulsa conferred the degree of doctor of mechanical engineering upon him in 1937.

Surviving Mr. Key are three children, Mrs. David Mackey, Mrs. Philip Abel, and Elmer A. Key. His wife, Mattie J. Key, died on June 24, 1942.

LEONARD KIPP (1868–1939)

Leonard Kipp, who died at his home in New Haven, Conn., on September 9, 1939, was born in Wuerttemberg, Germany, on April 12, 1868. He attended the Stuttgart Politechnium and after coming to the United States studied for two years at Eastman's Technical School, New York, N.Y. Subsequently he took several courses through the International Correspondence Schools.

The first record of Mr. Kipp's work as an engineer is for the years 1898–1900, when he was employed as a draftsman for the Farrell Foundry & Machine Co., Waterbury, Conn. The next two years were also spent in drafting work, with the Scovill Manufacturing Company, in the same city.

In 1902 he became assistant to the chief engineer of the Chase Rolling Mill Company, Waterbury. In this capacity he was instrumental in working out the design of the first hydraulic tube extrusion press in this country. Later, as engineer in charge of design for this company, he was responsible for the design and building of hydraulic rod presses and hydraulic draw benches, as well as for much other developmental work. It was during this period that he also obtained a patent for an operating valve for extrusion presses.

After leaving the Chase Company in 1916 Mr. Kipp, working for the United States government, planned and designed the entire plant of the Mueller Brass Company, at Port Huron, Mich. This project included a rod and tube mill, a power plant, a casting shop with all the necessary equipment, a production set-up for 75-mm shells and fuses, railroad sidings, and all underground equipment.

From 1919 to 1923 Mr. Kipp engaged in business for himself. Among other contracts he handled the engineering work for a complete hydraulic plant for the Bristol Brass Company, Bristol, Conn., and also one for the Michigan Brass & Copper Co., Detroit, Mich.

In 1923 he took a position as mechanical engineer in charge of brass mill engineering for the Western Cartridge Company, East Alton, Ill. In this capacity he was continuously engaged in the supervision of the design of special machinery for nonferrous rolling mills. After an illness in 1926 he went abroad in an official capacity for the Western Cartridge Company, visiting brass plants in Germany, Austria, and Switzerland. On July 1, 1937, he was transferred to the Winchester Repeating Arms Company, in New Haven, Conn., a plant which the Western Cartridge Company had purchased some years before. Here his work was chiefly concerned with modernizing the rolling mill of this plant, and the installing of new equipment. He continued in this capacity until July 1, 1939, at which time he was forced to resign because of ill health.

Mr. Kipp became a member of the A.S.M.E. in 1934. He was a Mason and Knight Templar. He is survived by his widow, Margaret Ann (McKelvey) Kipp, whom he married in 1890, and by four daughters, Mrs. Irving J. Granger, Mrs. Victor H. Budge, Miss Margaret Kipp, and Miss Pauline Kipp, and by a son, George Kipp.

C. RUSSELL KIRSCH (1896–1939)

C. Russell Kirsch, whose death occurred on November 11, 1939, was a native of Waterbury, Conn., where he was born on October 23, 1896, son of Theodore F. Kirsch, Sr., and Amelia A. (Kreger) Kirsch. He attended the local Webster Grammar School and Crosby High School, then studied for two years at Pratt Institute, Brooklyn, N.Y., graduating in 1917.

Immediately following his graduation Mr. Kirsch went to work as a draftsman for the Western Electric Company, Inc., New York, N.Y., where he was assigned to radio layouts for the English, French, and American governments. After a few months of this work he took a position as instructor in mechanical drawing in Public School No. 12 (Gary Vocational) and in the High School, Passaic, N.J., where he developed his own courses of instruction for the seventh and eighth grades and vocational classes.

From August, 1918, to August, 1919, he served in the U.S. Army as sergeant, first class, attached to Base Hospital No. 113, A.E.F., in charge of the personnel office for evacuating wounded soldiers home from France.

After his return to the United States, Mr. Kirsch was employed by the U.S. Rubber Co., in New Haven, Conn., as machine designer until June, 1921. From then until November, 1938, he was mechanical engineer for the Waterbury Manufacturing Company Division of Chase Companies, Inc., and its successor, the Chase Brass & Copper Co., Inc. His duties included making factory plans and layouts, designing tools and machines, and checking costs involved in the manufacture of various novelties and brass goods. During the last year of his life he served as foreman of the Press Department of the Lux Clock Manufacturing Company, Waterbury.

Mr. Kirsch was elected to junior membership in the A.S.M.E. in 1922 and promoted to full membership in 1930. He had been active in the work of the Waterbury Section of the Society. He was also a past-president of the Chase Foreman's Association, and belonged to St. Paul's Methodist Church, in Waterbury, and to the masonic and Odd Fellows fraternal orders. He was a member of Corporal Coyle Post of the American Legion.

Mr. Kirsch married Esther M. Ford, of Waterbury, in 1920 and is survived by her and their daughter, Eleanor Ford Kirsch, as well as by his parents and a brother, T. Franklin Kirsch, Jr., all of Waterbury.

JAMES ROSS KNOX (1895–1939)

James Ross Knox, consulting engineer, of Newport, Fife, Scotland, died on October 18, 1939. He was a native of Scotland and returned there in 1934 after having spent about twelve years in the United States. He became associate-member of the A.S.M.E. in 1931 and was automatically transferred to the grade of member in 1935.

Mr. Knox was born at Kirkcaldy, Fife, on April 18, 1895, son of Alexander and Barbara Robertson (Ross) Knox. His technical education was secured at the Dundee Technical College, where he took evening courses for three years, and through supplementary courses at New York University (Evening Engineering School) and the International Correspondence Schools. He served an apprenticeship as a machinist with the Urquhart & Lindsay Co., Dundee, prior to World War I and worked on textile machinery for that company for several years after the war. He was an ordnance artificer in the Royal Navy, having care of gunnery machinery, from 1914 to 1919.

In this country, Mr. Knox was maintenance engineer for the Clark Thread Company, Newark, N.J., for about two years, and then was associated with the Lord & Burnham Co., greenhouse designers and manufacturers, Irvington, N.Y. He worked on designs and estimates for complete heating systems for a number of companies in the East.

Mr. Knox was also a member of the Institution of Heating and Ventilating Engineers and the American Society of Heating and Ventilating Engineers. He married Janet Scott Carmichael, of Dundee, in 1923, and was survived by her and two children, Alexander James and Jean Anderson Knox.

EDWARD LENZ (1894–1938)

Edward Lenz, manager of distribution operation for the New York Steam Corporation, New York, N.Y., died on March 18, 1938. Mr. Lenz was born in Brooklyn, N.Y., on April 13, 1894, the son of Zachary and Katherine (Krumn) Lenz. He attended the Eastern District High School of Brooklyn and later took evening courses at Pratt Institute, Brooklyn, and the Polytechnic Institute of Brooklyn.

A recognized authority on the distribution of central station steam service, Mr. Lenz was a prolific writer for the National District Heating Association and author of the chapter on steam distribution in the association's handbook. In 1937 he was elected third vice-president of the association and was chairman of its Distribution Committee, 1928–1931, and a member of the committee during the remainder of his life. Mr. Lenz became a member of the A.S.M.E. in 1929 and served on the Sectional Committee on a Code for Pressure Piping from 1929 to 1938.

After leaving high school, Mr. Lenz, in December, 1912, entered the employ of the New York Steam Company, predecessor of the present New York Steam Corporation, and remained in their employ until his death. Following three years in the Engineering Department, he was transferred to the office of the chief engineer as an assistant, having charge of testing laboratories, his work including the testing of meters and equipment. In 1919 he became district superintendent in charge of construction, operation, and maintenance of the Corporation's distribution system in the Downtown District. Subsequently, in 1924, Mr. Lenz was appointed to the post of general superintendent of distribution, having charge of the operation and maintenance of the entire distribution system; he became manager of distribution operation in 1936. During the more than twenty-five years of his employment with the company, Mr. Lenz participated in the extension of a service that increased ten times during his active years and to which he made substantial contribution.

Surviving Mr. Lenz are his widow, Louise (Koenig) Lenz, whom he married in 1922, and two daughters, Elizabeth Louise and Joan Marie Lenz.

RICHARD CHARLES LEWIS (1896–1938)

Richard Charles Lewis, sales engineer of the Farrel-Birmingham Company, Inc., Ansonia, Conn., was killed when a United Airlines plane crashed on May 24, 1938, just before reaching its destination, the Cleveland Airport.

At the time of his death Mr. Lewis was manager of the rolling mill sales division of the Farrel-Birmingham Company in charge of sales of rolling-mill equipment and roll-grinding machines. Previously he had been connected with the engineering department as division engineer in charge of engineering of rolling mills, metal-working machinery, roll grinders, sugar machinery, and other heavy equipment. He had had engineering and sales experience on practically all products of the company and had been granted a number of patents for mechanical devices he had invented. He was widely known throughout the steel and nonferrous rolling-mill industries as an experienced and capable engineer with a thorough knowledge of the design and operation of rolling-mill equipment.

Mr. Lewis was born at Derby, Conn., on December 20, 1896, son of Edward Herbert and Emma (Donnell) Lewis. He received his early education in the Ansonia public schools and was graduated with a B.S. degree in mechanical engineering from Worcester Polytechnic Institute in 1919, immediately after which he entered the employ of the Farrel Foundry & Machine Co. as a draftsman.

His college course was interrupted during World War I when he entered the Air Corps in April, 1918. He was commissioned a second lieutenant and served as a pilot and flying instructor in aviation training camps in Georgia and Louisiana until after the armistice. He was enthusiastic about flying and frequently used the airlines on business trips.

Mr. Lewis became a junior member of the A.S.M.E. in 1921 and a member in 1933. He was also a member of the American Society for Metals. Fraternally, he was affiliated with Theta Chi fraternity, George Washington Lodge, F.&A.M., and Naugatuck Lodge, I.O.O.F. He was a member of William H. Gordon Post, American Legion, and of Christ Episcopal Church of Ansonia.

He is survived by his widow, Adelaide Louise (Beach) Lewis, whom he married in 1923, and a son, Franklin Beach Lewis, both now residing in Orange, Conn., as well as by his father and a sister.

ROBERT RAMSBOTTOM LISTER (1853–1938)

Robert Ramsbottom Lister, who died on November 16, 1938, was born on November 23, 1853, at Keighley, Yorkshire, England, son of Charles Lister and nephew of John Ramsbottom. His early education in home schools was supplemented later at a technical school and at Owens College in Manchester, where he began an apprenticeship in 1869 at the Gorton Foundry of Beyer Peacock & Co. Ltd., locomotive builders. His ability and trustworthiness led in 1872 to his being put to assisting in the delivery of locomotives to various points in England and on the Continent. Early in 1874 he entered the drawing office, where he remained until 1880. He then served successively as assistant works manager and chief of the machine shops until 1887, when he was appointed works manager at the Broughton Copper Co. Ltd., Manchester. He returned to the Gorton Foundry in 1890 to take up the position of chief draftsman and, on the formation of a new company, was made works manager, which position he held until he retired in 1904.

In 1905 he built the Greenbank Laundry at Gatley, Cheshire, which he carried on until his death. He joined the old Northern Counties Laundry Association in 1906 and was a member of the Council of that body, also president for a period and a very prominent worker in the Manchester branch of the Association. After the N.C.L.A. became merged in the National Federation of Launderers Ltd., he occupied the positions of representative of the National Council, member of the National Executive, vice-president, and, in 1926–1927, was president of the Federation. He was also chairman of the North Western District Council and one of the members responsible for the formation of the British Launderers Research Association.

He had been a member of the A.S.M.E. since 1894 and also belonged to the Institution of Mechanical Engineers and Manchester Association of Engineers.

He was a well-known Freemason, being Almoner and Past Master of Fellowship Lodge No. 3650, Past Provincial Grand Deacon of East Lancashire, and Founder and Second Principal of Fellowship Royal Arch Chapter No. 3650.

He married Agnes, the daughter of Michael Hodgson of Witherslack, Westmoreland, and they celebrated their Golden Wedding in 1932. His wife died in 1933, leaving two sons and two daughters, who survived him.

WALLACE FORREST MacGREGOR (1874–1939)

Wallace Forrest MacGregor, associated with the J. I. Case Threshing Machine Co., Racine, Wis., since 1898, died on June 18, 1939. He was born at Janesville, Wis., on February 19, 1874, son of Alexander and Mary (Milne) MacGregor. He prepared for college in the Janesville schools and was graduated from the University of Wisconsin with a B.S. degree in mechanical engineering in 1897. He received an M.E. degree the following year.

Mr. MacGregor began to acquire his experience with threshing machinery when he was only thirteen years old, working in the field during school vacations. By the time he entered college he knew

enough about wood and metal working to enable him to work as a machinist and patternmaker in the university shops to help defray his expenses. He went into the drafting room of the Case Company in July, 1898, and five years later was made superintendent of the Experimental Department. He continued to work on research, design, and testing of farm machinery all his life, and held some fifty patents in this line. He was mechanical engineer and director of the company at the time of his death.

During World War I Mr. MacGregor served as first lieutenant in Company I, 7th Regiment, Wisconsin State Guard, and was branch chairman of the Military Training Camps Association. He was a member of the Racine Board of Education for eight years, four years of which he served as its president. He was a member and trustee of the First Presbyterian Church of Racine.

Mr. MacGregor married Jessie Louise Hand, of Racine, in 1905, and is survived by her and a married daughter, Jean Douglas (Mrs. Richard D.) Miller.

He became a junior member of the A.S.M.E. in 1901 and a member in 1914. He had been a member of the American Society of Agricultural Engineers since 1910 and in 1914 served as its seventh president. Several of his papers were published in The Transactions of that Society. He belonged to the Delta Phi and masonic fraternities and the Racine Country Club, Rotary Club, and Somerset Club.

CHARLES MARTI (1882–1939)

Charles Marti, for many years designer in the Standard and Experimental Department of the Burroughs Adding Machine Company, Detroit, Mich., died on February 8, 1939. His widow, formerly Frida Dasen, of Berne, Switzerland, whom he married in 1920, and their daughter Veronica, returned to Switzerland after his death.

Mr. Marti was also a native of Switzerland, having been born in the canton of Basel on June 4, 1882, son of Karl Marti and Lina Marti-Rieder. He attended primary school in Basel, high school in Berne, and technical college in Zurich, being graduated there in 1906. During the next two years he was engaged in automotive truck design for Automobile Fabrik, at Orion, Zurich, then spent an equal period as mechanic, fireman, and locomotive engineer for the Chemin-de-fer Federal Suisse.

Mr. Marti first came to this country in 1910. He worked as draftsman for different automobile factories in Detroit for a year, after which he went into the Experimental Department of the Burroughs Adding Machine Company. His work on design there was interrupted by World War I in 1914. He returned to Switzerland and served as an engineering officer in the Swiss Army, in connection with the construction of the St. Gotthard and other fortifications, until 1917. From May of that year until August, 1919, he was superintendent of the Compagnie du Chemin-de-fer du Congo-Belge, in Africa, a road some 185 miles in length, with three roundhouses, two locomotive repair shops, and sixty locomotives. In addition to having charge of the road's supplies and maintenance, involving adjustments of equipment to the tropical climate, Mr. Marti bore some of the responsibilities, such as regulation of water supply, for the white settlements established in connection with the road.

After returning to the United States in 1920 Mr. Marti worked on design in the Experimental Department of the Ford Motor Company, at Dearborn, Mich., for about six months and in 1921 was superintendent of sewer construction in Detroit. He re-entered the employ of the Burroughs Adding Machine Company in 1922 and continued there until his death.

Mr. Marti had been a member of the A.S.M.E. since 1925.

ALLAN PATTON McCLINTOCK (1887–1939)

Allan Patton McClintock was born at Mt. Vernon, N.Y., on December 31, 1887, son of David Patton and Anna Clara (Yates) McClintock. He attended the Mt. Vernon public schools and was graduated from Cornell University in 1910 with an M.E. degree.

Following his graduation Mr. McClintock was employed at the Homestead (Pa.) works of the Carnegie Steel Company, for something over a year, the latter part of the time as assistant to the steam engineer. In the fall of 1911 he went with the Babcock & Wilcox Co., at Bayonne, N.J. After some shop experience on boiler testing, he was transferred to the proposition department, where his duties included designing and estimating of boilers, stacks, superheaters, and other apparatus. He continued in that work until the spring of 1916, then spent about a year in the sales department of the Imperial Oil Co., Ltd., Toronto, Ont., Can., as engineer in connection with the mechanical use of oil and petroleum products. There followed a short period devoted to the reorganization of the plant of the Akron Company, Long Island City, N.Y., a machine shop for which in 1914 he had designed a steam power plant.

In July, 1917, Mr. McClintock was commissioned a first lieutenant in the Ordnance Department, U.S.A., and assigned to the arsenal at Frankford, Pa., where he was stationed until the end of 1918, directing artillery ammunition production and drilling the ordnance detachment at the arsenal.

During the early part of 1919 Mr. McClintock assisted the Philadelphia Claims Board in the settlement of claims growing out of the cancellation of war contracts after the armistice. Then he took a position as representative of the Locomotive Superheater Company, New York, with which he continued until 1922. For the next five years he was engaged in industrial construction work for Geo. E. Batcheller, Inc., New York, and subsequently he was sales manager for the eastern part of the United States for the Feather-Stone Company, with headquarters at New York, for two years. He then served successively as New York representative for the C. H. Cowdrey Machine Works, of Fitchburg, Mass., builders of special automatic machinery; the Caterpillar Tractor Company, as Virginia representative, located at Richmond; and the Beckwith Machinery Company, of Pittsburgh, Pa., handling sales of Diesel engines in Pennsylvania.

Mr. McClintock was inactive during the latter part of his life. After suffering a heart attack at his home in Mt. Vernon he resided with relatives at Meadville and Cochranton, Pa. His death occurred on October 6, 1939, at the Veterans Hospital in Aspinwall, Pa. He was unmarried. An aunt, Miss Jennie E. Yates, of Meadville, survives him.

Mr. McClintock became an associate-member of the A.S.M.E. in 1913 and was promoted to the grade of member in 1920.

FRANK RAYMOND McGEE (1873–1939)

Frank Raymond McGee, whose death occurred on December 5, 1939, was born on July 9, 1873, at McGees Mills, Clearfield County, Pa., son of Henry Lafayette and Agnes Ann Rose McGee. He attended the local country school and spent two years in the Preparatory Department of The Pennsylvania State College. He secured his B.S. degree in the mechanical engineering course at the college in 1897.

In December of that year Mr. McGee went to work in the drafting room at the Edgar Thomson Works, Bessemer, Pa., of the Carnegie Steel Company. Both this company and the National Steel Company, with which he was later employed, were acquired by the U.S. Steel Corp., and he was connected with them and with the Carnegie-Illinois Steel Corporation, a subsidiary of the U.S. Steel Corp., continuously until his death. For many years he had been at the works located at Mingo Junction, Ohio, serving as mechanical engineer there since 1905. During the course of his work he invented a thermal expansion goggle valve and open joint checkers, which he listed as the more important of his inventions, and also a flexible coupling, chimney valve, gas cleaner, and a single-pass hot blast stove.

Mr. McGee had been a member of the A.S.M.E. since 1912. Other societies to which he belonged were the American Iron and Steel Institute and the Engineers Society of Western Pennsylvania. He married Abbie Priscilla Ault, of Steubenville, Ohio, in 1904, and is survived by her and a daughter, Mary Agnes (Mrs. Lewis) Gray.

ARTHUR WILHELM MERKEL (1883–1939)

Arthur Wilhelm Merkel, vice-president in charge of production and design of the Continental Gin Company, Birmingham, Ala., died on May 6, 1939. He was a native of Alabama, having been born at Eureka, Talladega County, on August 1, 1883. His parents were William A. and Ada Brisbane (Arthur) Merkel.

Mr. Merkel obtained his technical education at the Alabama Polytechnic Institute, from which he was graduated with a B.S. degree in mechanical engineering in 1904. He entered the employ of the Continental Gin Company immediately following his graduation, being one of three men in his class recommended, in response to a request from the company, to work for it and learn the business. After experience in erecting the company's special cotton ginning machinery as well as other equipment, he was transferred to one of the factories. During ensuing years he learned all manufacturing details of the business and was given increasing responsibility, serving successively as assistant foundry superintendent, assistant to the factory superintendent, and head of the finishing department of the Avondale factory. In 1914 he was made assistant general superintendent of the company's factories, located in different parts of the South, with headquarters in Birmingham. For three years he had charge of designing new machinery for cotton gins, cottonseed oil mills, and power plants, and a full line of transmission machinery. He also engaged in capacity and efficiency tests of new machines, some developed for war work.

When the United States entered World War I in 1917 Mr. Merkel was commissioned a captain in the Coast Artillery, and served overseas in the antiaircraft section. After his discharge in 1919 he returned to the Continental Gin Company as superintendent of its plant at Atlanta, Ga. He was transferred to the Birmingham plant in the same capacity in 1924 and made general superintendent in 1930. He had been vice-president in charge of production and design since 1934. Several patents on gin machinery were taken out by him.

Mr. Merkel had been a member of the A.S.M.E. since 1921. Subsequent to his retirement from active war service he entered the Officers' Reserve Corps, in which he had advanced to the rank of colonel. He belonged to the masonic fraternity, Presbyterian Church, and Birmingham Country Club.

Mr. Merkel married Nora Izetta Duke, of Birmingham, in 1908 and is survived by her and two married daughters, Lona Brisbane (Merkel) Croft, and Lois Izetta (Merkel) Parker.

ARTHUR EUGENE MICHEL (1880–1939)

Arthur Eugene Michel, owner of the technical advertising firm of A. Eugene Michel and Staff, New York, N.Y., died of heart disease at his home in Douglaston, L.I., N.Y., on November 9, 1939. He had been engaged in advertising work since 1905. After securing a B.S. degree from Rose Polytechnic Institute in 1903 he was employed as designing draftsman with the Diamond Chain & Manufacturing Co., Indianapolis, Ind., and for a short time was with the Ewart Manufacturing Company, of the same city. While in college he had spent two summers in electric railway work with C. O. Mailloux, New York consulting engineer, and in 1905 he returned East and took a position as assistant manager of publicity for the International Steam Pump Company, of Harrison, N.J. Subsequently, before going into business for himself, he was office manager of Geo. N. Gibson Co., advertising agents, New York.

Mr. Michel was born at St. Louis, Mo., on March 4, 1880, son of Henry and Louise D. Michel. Three years after his graduation, Rose Polytechnic Institute conferred an M.S. degree upon him. In addition to his engineering and advertising work, he was greatly interested in philately, specializing in entires and government stationery. His collection of these items, considered one of the best in the United States, received a first award at the Philatelic Exposition in New York in 1935 and has been maintained in its entirety at the Smithsonian Institution in Washington. He was a member of the Collectors Club, New York. He wrote one book on philately, "Roving the Stamp World," and several others, including "The Use of Steel Sheet Piling," "Raising of the United States Battleship *Maine*," and "Steam Heating."

Surviving Mr. Michel are his widow, Lisette Albertine (de Saver) Michel, and a daughter, Celeste Michel.

Mr. Michel became a junior member of the A.S.M.E. in 1906 and an associate of the Society two years later.

JOHN FISHER GARR MILLER (1877–1939)

John Fisher Garr Miller, vice-president of the B. F. Sturtevant Co., Hyde Park, Boston, Mass., died on December 9, 1939, of a heart attack at his home in Brookline, Mass. He is survived by his widow, Helen B. (May) Miller, whom he married in 1934, and by two brothers.

Mr. Miller was born at Nineveh, Johnston County, Ind., on March 23, 1877, son of John Chapman and Elizabeth Ann (Garr) Miller. After a private preparatory education he entered Purdue University with the Class of 1903. During his college years he was captain of football, track, and basketball teams, and secured four letters in athletics. He was also elected to Tau Beta Phi, honorary engineering fraternity.

After his graduation with a B.S. degree in mechanical engineering, Mr. Miller served an apprenticeship in the shops and drafting room of the Chicago & Eastern Illinois R.R., at Danville, Ill., and with the Penberthy Injector Company at Detroit, Mich. Subsequently he was connected with several design and construction projects, including a heating system for a factory at Brazil, Ind., for the Wood Turret Machine Company; a lumber drying plant for the Cooper Carriage Wood Work Company, St. Louis, Mo.; a heating system for the Crystal City (Mo.) plant of the Pittsburgh Plate Glass Company; and a heating and power plant for the high school and negro manual training school at Muskogee, Okla.

He then became engineering salesman and manager of the St. Louis office of the American Blower Company, of Detroit, Mich., with which he was connected until 1933, becoming general sales manager, vice-president, and a director of the company. He had been vice-president, in charge of sales, advertising, and sales promotion, of the B. F. Sturtevant Company since 1933, and took particular pride in the effectiveness of the student sales engineering course which he inaugurated in 1934.

Mr. Miller was widely known and highly regarded in the fan and air conditioning industry. A member of the A.S.M.E. since 1910, he served from 1919 to 1931 on the Power Test Codes Individual Committee No. 9 on Displacement Compressors and Blowers. He was a past-president and director of the National Association of Fan Manufacturers, chairman of the board of directors and past-president of the Air Conditioning Manufacturers' Association, and past-president of the Industrial Unit Heater Association. He was a member of the American Society of Heating and Ventilating Engineers and of the University Club, Boston, and belonged to several country clubs in that vicinity.

GEORGE HERBERT NELSON (1901–1939)

George Herbert Nelson, a junior member of the A.S.M.E. since 1926, was drowned at Jones Beach, L.I., N.Y., on June 11, 1939.

Born in Worcester, Mass., on September 23, 1901, son of Peter A. and Paulina (Krafve) Nelson, he was graduated from the South High School, Worcester, and from Worcester Polytechnic Institute, receiving a B.S. degree in mechanical engineering in 1923. To familiarize himself with rolling mill machinery, he worked for a few months in the Assembly Department of the Morgan Construction Company, Worcester, then went into the Engineering Department of the company as a detail draftsman and designer of rolling mill machinery.

During the early part of 1925 Mr. Nelson took a position as special investigator at the National India Rubber Company, U.S. Rubber Co., Bristol, R.I. He carried on studies to improve production by the elimination of waste material and labor in the wire and shoe divisions of the company. After about two years on this work he went to the Sayles Finishing Plants, Inc., Plant A, at Saylesville, R.I., where he was employed first as a time study man and systematizer. He was later promoted through several departments to the position of superintendent of the dye works and related departments, a position which he held for about five years.

In September, 1933, Mr. Nelson entered the Harvard Graduate School of Business Administration as a candidate for a M.B.A. degree, which he received in June, 1935. Since then he had been employed as industrial engineer by the Eastman Kodak Company, Rochester, N.Y.

Mr. Nelson became a junior member of the A.S.M.E. in 1926.

CHARLES LADD NORTON (1870–1939)

Charles Ladd Norton, director of the Division of Industrial Co-operation at the Massachusetts Institute of Technology since 1921, a widely known inventor and engineer, died at his summer home in Annisquam, Mass., on September 8, 1939.

A pioneer in fire-prevention studies, Dr. Norton was the inventor of asbestos shingles and homogeneous asbestos-cement building sheets used in most modern structures. His inventions in this line paved the way for the asbestos industry.

Dr. Norton became prominent during World War I as the first person in the United States to manufacture magnesium metal for commercial purposes. The metal became an important constituent of flares used by the Army Air Service. Previously, magnesium metal had been manufactured only in Germany.

In association with the late Henry M. Whitney, of Boston, Dr. Norton collaborated with officials of the Johns-Manville Corporation in the manufacture of transite, a material widely used in the building industry to insure corrosion-proof water pipes. Among his many contributions to industry was a machine for making silica brick which superseded the old hand-molding method. His process is now used universally. He helped develop the application of X-rays to medicine and surgery in this country and was distinguished for early investigations in this field with Dr. Francis H. Williams, of Boston.

Altogether, Dr. Norton held more than one hundred American and foreign patents relating to the economies of heat and the diminution of fire loss. He was the director of many corporations and the founder of the Norton Laboratories, in Lockport, N.Y. His published papers, beginning with "The X-rays in Medicine and Surgery" in 1896, range over almost the entire field of industrial physics and number more than fifty.

Dr. Norton was born on December 11, 1870, at Springfield, Mass., son of Francis and Jennie Maria (Atwater) Norton. He attended the local schools and was graduated from the Massachusetts Institute of Technology in 1893, with an S.B. degree. In the same year he joined the M.I.T. physics department and remained a member of the faculty until his death. He became successively professor of industrial physics, director of the research laboratory of industrial

physics, and head of the physics department, before becoming director of the Division of Industrial Co-operation.

Dr. Norton became a member of the A.S.M.E. in 1910. He was a fellow of the American Academy of Arts and Sciences and a member of the Society for the Promotion of Engineering Education, American Physical Society, American Chemical Society, American Association for the Advancement of Science, American Ceramic Society, National Fire Prevention Association, American Society for Testing Materials, and many other organizations.

Surviving are three sons, Frederick H. Norton, of Winchester, Mass., John T. Norton, of Cambridge, Mass., and Charles L. Norton, Jr., of New York, and three daughters, Mrs. Joseph Bacheller, of Los Angeles, and Miss Margaret Norton and Miss Dorothy Norton of Boston. His wife, Mrs. Frances (Torrey) Norton, died in 1936. They were married in 1895.

FRED R. PATCH (1853–1938)

Fred R. Patch, who died on January 20, 1938, in Rutland, Vt., was born there on October 15, 1853, son of Joseph Lewis and Annette (Lull) Patch. He attended public schools in Rutland and Proctor, and his first work was with the Sutherland Falls Marble Company of Vermont, which had been organized by Redfield Proctor about 1870. In an address made by Mr. Patch at a conference in Proctor in June, 1926, he referred to one of his early assignments, as follows:

"Fifty years ago last fall Colonel Proctor sent me to the Hoosac Tunnel to take out and load on the cars about one hundred carloads of machines,—engines, boilers, air compressors, rock drills,—that had been used in building the tunnel. Some of the air compressors came here and were in operation for several years at the south end of the lower mill. There were no trains passing through the tunnel when I first got there and I walked from North Adams, through the tunnel, seven miles to the East End Shops, back and forth, a great many times. After a couple of months they began running one train through the tunnel from North Adams each morning and back in the evening. I still have the note from the state treasurer, Mr. Bond, to the train conductor, Mr. Miller, that passed me through the tunnel many times on this first train."

The Sutherland Falls Marble Company was combined with the Rutland Marble Company in 1880 to form the Vermont Marble Company, with which Mr. Patch was connected until 1890, rising to the position of general superintendent.

For a short time after leaving the Vermont Marble Company Mr. Patch was general superintendent of the Sheldon Marble Company in West Rutland. During the latter part of 1891 he entered into partnership with Newman K. and George T. Chaffee, of Rutland, under the name of F. R. Patch & Co. They purchased the foundry and machine shop of Mansfield and Stimson, who had manufactured stone working machinery. Less than a year afterward, the business was consolidated with the Charles P. Harris Manufacturing Co., and a corporation was formed under the name of the F. R. Patch Manufacturing Co., specialists in manufacturing machinery for working marble, granite, and stone. Mr. Patch served as president of the company until his retirement in 1933. He developed many new machines for stone working and lived to see them in use throughout the United States and in many other countries.

In 1917 the F. R. Patch Manufacturing Co. purchased the Glens Falls (N.Y.) Machine Works, which manufactured pulp and paper machinery, and Mr. Patch became its president, also. Later he was president for a number of years of the Madras Marble Corporation, of Sylacauga, Ala.

In the fall of 1927 the F. R. Patch Manufacturing Co. was consolidated with the Julius Wegner Machine Works, of Long Island City, N.Y., under the names of Patch-Wegner Company, Inc., Rutland, and Patch-Wegner Corporation, Long Island City. Mr. Patch was president of the former and vice-president of the latter.

Mr. Patch had written articles regarding progress in the stone and marble industry for publications in that field. He had been a member of the A.S.M.E. since 1929 and belonged to the Vermont Society of Engineers. He was the first president of the town of Proctor; commissioner of public safety in Rutland for several years beginning in 1909; commissioner of public works for Rutland County, 1915–1916; a former vice-president and director of the Rutland County National Bank; and past-president of the Evergreen Cemetery Association.

Mr. Patch is survived by his widow, Cigrid B. Patch. His first wife, Abbie (Loveland) Patch, whom he married in 1875, died in 1908.

JOE W. PIERSON (1893–1939)

Joe W. Pierson, who died on February 5, 1939, was born at Aberdeen, S.D., on May 27, 1893, son of Frank and Emma (Hamm) Pierson. He attended Aberdeen schools, including normal school, and was graduated from the University of Minnesota with a B.S. degree in 1919. He was in training for naval service during the summer of 1918, until the armistice was signed.

From the time of his graduation until his death Mr. Pierson was employed by the Commonwealth Edison Company in Chicago, Ill. Beginning as technical assistant on boiler and turbine testing, he was made assistant boiler room engineer at the Quarry Street Station in 1921 and at the Calumet Station two years later, boiler room engineer at the Crawford Avenue Station in 1924, and efficiency engineer of generating stations in 1934. He was serving in this capacity at the time of his death.

Mr. Pierson became a member of the A.S.M.E. in 1930. He is survived by his widow, Laura (Curtis) Pierson, whom he married in 1920, and by a daughter, Marjorie Ann Pierson.

JOSEPH HORACE POUND (1890–1942)

Joseph Horace Pound, professor of mechanical engineering at the Rice Institute, Houston, Texas, and consulting mechanical and petroleum engineer, died on May 23, 1942. He was born on June 24, 1890, at Hannibal, Mo., son of William L. and Zoretta (Burbank) Pound. He attended the Hannibal public schools and was graduated from the University of Missouri in 1913 with the degree of Bachelor of Science in Mechanical Engineering. Postgraduate work in summer sessions at the Universities of Missouri and Wisconsin led to an M.E. degree from the former in 1921.

After being employed with the Westinghouse Machine Company (now Westinghouse Electric & Manufacturing Co.), East Pittsburgh, Pa., in various departments and serving on the staff of the Casino Technical Night School (now Westinghouse Technical Night Schools), he joined the faculty of the Rice Institute in 1914. He had charge of the organization of the Department of Mechanical Engineering, including selecting, purchasing, and installing laboratory and shop machinery, building necessary structures, and forming the courses of instruction. He was head of the department until his death, except for the years 1917 to 1919, while serving in the U.S. Army. He was made assistant professor in 1919 and professor ten years later. He was a member of the faculty committees on Honours Courses and Advanced Degrees and on Examinations and Standings, and of the Faculty Club of the Institute.

An authority on petroleum production problems, Professor Pound contributed many papers and articles to trade and technical magazines serving that field. Nearly all of his summer vacations were spent in special work for various companies, including the Gulf Pipe Line Company, Reed Roller Bit Company, Texas Company, and Hughes Tool Company, all of Houston. He did much important work on design problems for these companies.

Professor Pound became a junior member of the A.S.M.E. in 1915 and a member in 1923. He was responsible for establishing the Society's Student Branch at Rice Institute in 1926 and served as its honorary chairman for many years. He was a member of the executive committee of the Houston (now South Texas) Section of the Society from 1925 to 1935, and its chairman in 1931-1932.

He was also an active member of the Society for the Promotion of Engineering Education and of the Houston Philosophical Society, of which he was treasurer in 1925 and president in 1933. He belonged to Tau Beta Pi and Sigma Xi, honorary scholastic fraternities, and was instrumental in founding student chapters of those organizations at the Rice Institute.

During World War I Mr. Pound entered the army as a private in the Ordnance Department. He attended Ordnance Schools and Engineer Officers' Training Camps and was commissioned a second lieutenant and sent overseas with the 546th Engineers in 1918. He served on highway work in the Argonne, St. Mihiel, and other sectors until after the armistice and then was an instructor at the A.E.F. University for several months. He left the service in July, 1919.

Professor Pound married Ruth Robinson in 1919 at Graham, Texas, and is survived by her and three children, John H., a student at Rice Institute, and David R. and Mary E. Pound, students in the Houston public schools.—[Memorial prepared by R. R. Crookston, Houston, Texas. Mem. A.S.M.E.]

EWALD PYZEL (1901–1939)

Ewald Pyzel was born at Tjepoe, Java, Dutch East Indies, on March 31, 1901, son of Daniel and Maria Catherina (von Glahn) Pyzel. After attending technical high school at The Hague, Netherlands, he came to the United States. He was graduated from Stanford University in 1925 with a B.S. degree in mechanical engineering.

Mr. Pyzel's first position after graduation was that of technical assistant at the Wood River (Ill.) Refinery of the Roxana Petroleum

Corporation (now Shell Oil Co., Inc.). He left there in 1929 to study the design of European synthetic ammonia and gasoline plants. In 1930 he was charged with the design and construction of a nitrogen fixation plant for the Shell Chemical Company at Pittsburg, Calif., and he superintended the operation of this plant from 1931 until his death. He held patents on a process and apparatus for the separation of liquids from gases, a process for the vapor phase hydrogenation of olefin polymers, and catalytic converters.

His widow, Mabel (Johnson) Pyzel, whom he married in 1925, and two children, Mary Catherine and Ewald Daniel, survive him, and also a brother, Frederic Pyzel, all of Piedmont, Calif. His death occurred on October 12, 1939, at the University of California Hospital, San Francisco, from a brain tumor.

Mr. Pyzel became a junior member of the A.S.M.E. in 1926 and also belonged to the Verein Deutscher Ingenieure. His interests outside his profession included painting, drawing, and the history of shipbuilding.

CHARLES DeLOS RICE (1859–1939)

Charles DeLos Rice, who had been issued some seventy-five patents on a variety of inventions, many relating to bicycles and typewriters, died on September 10, 1939, after a long illness. Retired from the Underwood Elliott Fisher Company (formerly Underwood Typewriter Company), with the title of vice-president in 1929, because of poor health, he was later able to take up further work on his inventions, which included improvements on pneumatic tires, gear-cutting machines, forging machines, milling and drilling machines, and a great variety of single-purpose mechanisms.

Mr. Rice was born at Auburn, N.Y., on April 15, 1859, son of Benjamin and Harriet M. Rice. His formal education, extending only through grammar school, was supplemented by home studies. As a general shop worker over a period of about ten years he became proficient in machine construction and toolmaking. He was associated during part of this time with the Caligraph Typewriter Company, at Corry, Pa. He moved to Hartford, Conn., with this company in 1885 and remained with it until 1888, when he joined the Yost Writing Machine Company at Bridgeport, Conn., while they were developing their machine. This led, in 1890, to the position of chief engineer of the Pope Manufacturing Company, of Hartford, builders of the Columbia bicycle. Located at the Columbia factory, he also guided the work of the company's allied plants.

Mr. Rice resigned this connection to become superintendent, on January 15, 1901, of the Underwood Typewriter Company, then located in Bayonne, N.J., but later moved to Hartford. He was made general manager in 1907 and as such subsequently directed the activities of more than five thousand employees.

Mr. Rice won honors at two expositions. At the one in Paris in 1900 he was awarded a medal for bevel gear-cutting machines, and in 1915, at the Panama-Pacific International Exposition in San Francisco he was given a gold medal for services rendered in the production of high-grade typewriters.

Mr. Rice had been a member of the A.S.M.E. since 1907. He had resigned from The Franklin Institute, to which he belonged for many years. He had served one term as councilman for the city of Hartford, and was a member of its school board for six years. Over a long term of years he had served on many directorates.

Surviving Mr. Rice are his widow, Anna C. (Hoagland) Rice, whom he married in 1882, and a daughter, Edna (Rice) Leavitt.

PAUL K. ROGERS (1889–1938)

Paul K. Rogers, president and treasurer of the Skinner Chuck Company, New Britain, Conn., accidentally fell from a fourth story window of the factory on January 11, 1938, and died before reaching the hospital.

Mr. Rogers was born in New Britain on February 4, 1889, the son of Daniel O. and Emma C. Rogers. After completing his studies at the New Britain High School he attended Princeton University for a year, then went to work for the Skinner Chuck Company as a clerk in the superintendent's office. Subsequently he spent some time in the Cost Department and also in the Purchasing Department. He was made treasurer of the company in 1915 and president in 1931.

Mr. Rogers organized a new bank in New Britain, known as the City National Bank, and was its president for six years until it was taken over by the New Britain National Bank in 1932. He was a deacon at the South Congregational Church of that city for a number of years, an office which both his father and grandfather had held. He was also much interested in civic affairs.

He became an associate of the A.S.M.E. in 1934 and had been a member of the Society of Automotive Engineers since 1932. He is survived by his widow, Greta (Clark) Rogers, whom he married in 1911, and by a son, Paul K. Rogers, Jr., of New Britain, and three daughters, Greta, of New Britain, Marjery, of New York, N.Y., and Jane (Rogers) Beebe, of Cornwall, Conn.

CHARLES WILLIAM RUSH (1886–1938)

Charles William Rush, who died on September 23, 1938, was born in London, England, on November 28, 1886, son of Charles William and Martha Ann (Bougen) Rush. After taking a course in mechanical engineering at the East London College of Engineering, he served an apprenticeship with the India Rubber Gutta Percha & Telegraph Co. in London, securing machine shop, drafting, and other experience. The following year he was an inspector for Robey & Co., Lincoln, England, in connection with high-speed engines, air compressors, and winding equipment for collieries. During the next three years he held the position of assistant chief inspector with the British Thomson Houston Company, at Rugby, also engaging in the design of tools, gages, and fixtures, and then he was in charge of machine shops for Crossley Bros., Manchester, directing work on various types of engines and turbines. At the outbreak of World War I he was appointed assistant superintendent and estimated and planned various war contracts and installed departments for producing naval ammunition.

Following the war, Mr. Rush became production manager for the Meccano Company, Ltd., Liverpool, in charge of the entire factory, employing some fifteen hundred people engaged in the manufacture of small electric motors, transformers, electric and mechanical trains, and other electric and mechanical toys. He contributed much to the success of the company through his design of special machines and layout work for mass production. In 1922 he was transferred to Paris as general superintendent of Meccano (France) Ltd., responsible for the establishment of another factory for such products. After supervising operations there for a time he came to the United States in 1924 to locate a factory at Elizabeth, N.J., and served as its general superintendent until 1930.

Mr. Rush left the Meccano Company to become assistant superintendent of the Meter Department of the Worthington Pump Company at Harrison, N.J., but after a few months there he went to Waterbury to take the position of superintendent of the Waterbury Manufacturing Company (now a subsidiary of the Chase Brass & Copper Co., Inc.), with which he was connected until his death, serving as plant engineer during the latter part of the time. He reconstructed and rearranged the various departments and installed new processes.

Mr. Rush had been a member of the Rugby Engineering Society and Manchester Association of Engineers, in England. He became a member of the A.S.M.E. in 1930 and served as secretary-treasurer of the Waterbury Section from 1936 to 1938. He also belonged to the Connecticut Society of Civil Engineers and masonic fraternity.

Surviving him are his widow, Eleanor S. (Alford) Rush, whom he married in London in 1911, and their daughter, Edna Nellie (Rush) Crane.

LEE GRISWOLD SHARPE (1893–1935)

Lee Griswold Sharpe, who became an associate of the A.S.M.E. in 1931, died suddenly on April 28, 1935, at Portland, Ore., from an acute heart attack, while on a business trip. He had been general sales manager of the Atlantic Paint Company, New York, N.Y., since 1918, covering territory west of the Mississippi, with headquarters at first in Oakland, later in Los Angeles, Calif.

Mr. Sharpe was born on October 19, 1893, at Denver, Colo., son of Alexander and Rachel Jane Sharpe. When he was two years old the family moved to San Francisco, where he was educated in the public schools. Prior to his connection with the Atlantic Paint Company he was manager of the Oakland Phonograph Company, Oakland, and of the Phonograph Department of the Benj. Curtez Music Company, San Francisco. He was an accomplished musician, playing the piano and trumpet and singing in various musical organizations. He had been tenor soloist in several churches, including the First Baptist Church of Oakland and the Episcopalian Church of the Advent, of San Francisco, of which he was a member. He was a member of the Glendale (Calif.) Lodge of Elks.

Mr. Sharpe married Mable Marshall, in Oakland, in 1917, and is survived by her. A sister, Gertrude (Sharpe) Martin, of Oakland, also survives him.

EDWIN COUPLAND SHAW (1863–1941)

Edwin Coupland Shaw, a resident of Akron, Ohio, since 1893, died at his home in that city on November 25, 1941, at the age of seventy-eight, noted both for his engineering and industrial work and his humanitarian and philanthropic projects.

Mr. Shaw's first position in Akron was that of superintendent of the Akron Light & Power Co., for which he was well fitted by a number of years' experience in the electrical industry. Born in Buffalo, N.Y., on February 1, 1863, the son of Edwin A. Shaw, a manufacturer of lumber and lumber products, and Clara (Coupland) Shaw, he attended public schools in Buffalo and entered the Sheffield Scientific School of Yale University. After securing his Ph.B. degree in 1886, he spent one season as assistant engineer on a cargo steamer on the Great Lakes. He then had a year with Otis Brothers & Co., elevator manufacturers, New York, N.Y., followed by a year in drafting work, part of the time with Charles M. Morse, consulting mechanical engineer, of Buffalo. In 1888-1889 he was engineer and draftsman, giving particular attention to gas engines, for the Binghamton (N.Y.) Hydraulic Power Company. He continued work of this character under his own name, with an office in Binghamton, until early in 1891, when he became general superintendent of the Thomson-Houston Electric Light & Power Co., Buffalo. During about two years there he reconstructed some of the stations.

With this background, Mr. Shaw took up his work in Akron. His ability was noted by the superintendent of the B. F. Goodrich Co., who persuaded him to join that organization on January 1, 1895, as mechanical and electrical engineer. His rise in the company was rapid. He became assistant superintendent in 1902, general manager four years later, and vice-president in charge of all factory operations in 1912. He retired from active management in 1919, but remained on the board of directors until 1926.

J. Henry Vance (Mem. A.S.M.E.), who entered the employ of the B. F. Goodrich Co. as a draftsman in 1894 and rose to the position of superintendent of power, has written the following account of Mr. Shaw's electrification of the Goodrich plant during his first years there.

"Here Mr. Shaw found a fertile field for the exercise of his ability as the industry was growing at a very fast pace, due largely to the pneumatic tire then coming into production for bicycles, and later for motorcycles and automobiles.

"Buildings had to be built, power facilities enlarged, and equipment developed to meet the ever-increasing demand for production.

"The principle type of buildings then in use had brick walls with wooden beams, columns, and floors. Mr. Shaw, seeking a more substantial and fireproof type of factory building, placed a contract for a reinforced-concrete building, the first of this type constructed in Akron. This building is still in use for manufacturing, and practically all later expansion was of the same type.

"The power plant at Goodrich, when Mr. Shaw took charge, consisted of about thirty steam engines and ten return-tubular boilers of 100-lb pressure. These engines were scattered all over the plant and ranged in size from 4 to 300 hp. They drove the rubber machinery by means of belting and line shafts.

"Mr. Shaw early became convinced that in order to take care of the rapidly increasing power demands and to have a system flexible enough to make possible an arrangement of equipment which would give a much higher efficiency, it would be necessary to consolidate the steam generating plants, which by this time consisted of three separate boilerhouses, and to generate sufficient electricity to drive all equipment, including mills and calenders, by motors and replace all gas by electric lighting.

"He made a careful and comprehensive study of this whole subject, and having no data of any kind to guide him as to the amount of power required to operate a gang of mills or an individual calender, he had carried out a long series of tests to establish facts on power requirements and, at the same time, looked into the use of alternating current as a means of lighting and power.

"The result was that in 1899, a layout of a consolidated powerhouse was completed and contracts placed for building boilers, coal-handling equipment, two 500-kw Westinghouse alternating-current, 60-cycle, 2-phase, 220-volt generators (each direct-driven by a cross-compound Harrisburg engine), and a synchronous rotary converter to furnish direct current for operation of calenders, as this type of direct-current drive allowed for a rather wide variation of speed of the calenders which had hitherto had but two speeds.

"All of this electrical equipment was so new as to type in this country, and the first of its kind installed west of Pittsburgh, that when the contract was written by Westinghouse a clause was inserted that stated that should the motor or generators not function to the full satisfaction of the B. F. Goodrich Co., the Westinghouse company would, at their own expense, remove all the alternating generators and motors and replace them with direct-current equipment; but when the plant was completed and started up in August, 1900, it was a complete success. The expansion of power demand was so rapid from then on that in 1902 a 400-kw turbine-driven generator, also the first of its kind shipped west by the Westinghouse company, was installed, and before the installation was finished, a 750-kw turbine-driven generator was ordered. Successive and larger turbines were installed at intervals of about two years until by 1907 five in all had been installed. At this time, it was decided to purchase all additional power required, as available condensing water facilities were exhausted."

Walter H. Allen, of Grosse Pointe, Mich., also associated with Mr. Shaw over a period of many years, refers to the electrification of the Goodrich plant as an "outstanding accomplishment which has stood the test of years and still remains best practice. Mr. Shaw conceived and directed the first application of central-station practice to rubber industry requirements. It was an enormous undertaking, requiring no small amount of foresight and confidence, and was carried through to a most successful conclusion in record time."

Charles F. Scott (Mem. A.S.M.E.), engineer at the Westinghouse works at the time of the electrification of the Goodrich plant, writing for the *Yale Scientific Magazine*, spring of 1942, also speaks of the task as a pioneer job, the plan for which was "ingenious, simple, and admirably adapted for the several services." Mr. Shaw, he says, was "a plain and quiet man; but he understood his problem and knew what he wanted."

Regarding other improvements inaugurated by Mr. Shaw, Mr. Vance writes:

"Mr. Shaw early recognized that the method of curing rubber goods in use when he entered the business was very wasteful of steam, and he did not hesitate to apply steam traps in place of hand-operated blow-off valves to remove the condensate from the vulcanizers, making the first installation of this kind in this country. He also introduced what is now called the quick-opening door, used throughout the country for opening and closing vulcanizers. He recognized the advantages of the principles of operation, and the economy of space requirements of centrifugal pumps, and purchased one of the first put out by the Worthington Pump & Machinery Corp. He introduced the use of electric clutches to disconnect quickly the rubber mills from their driving motor, should an employee become caught between the rolls."

Much has been recorded in the public press concerning Mr. Shaw's outstanding services as a humanitarian and philanthropist. But Mr. Shaw is said to have had a horror of being regarded as what he called "a long-haired uplifter." Dr. Scott has ably summarized the record of these services as follows:

"As an industrial manager he was a pioneer in the betterment of employee relations; interest in the health of employees extended to public health work and the establishment of a tuberculosis sanatorium, recently named for him. He was connected with scores of enterprises from Scouts to State Board of Pardons and Parole, and numerous state boards having to do with welfare. In civic leadership he was cited as one of Akron's finest citizens and a prominent contributor to everything he undertook."

With broad vision and foresightedness, Mr. Shaw recognized the importance of community and industrial health and he attacked these problems with the same energy and thought that he applied to those of engineering.

In fact, he used the same engineering principles in their solution that he had used in solving those of steam and electricity.

Careful planning, cautious testing, and thoughtful consideration of the methods to follow in establishing and maintaining a sure control led finally to the conversion of the ordinary county tuberculosis sanatorium which has been mentioned into one of national reputation; and of a county control of this disease that has reduced its mortality to a minimum. Because of his outstanding services in its behalf as a trustee, the name of the Sanatorium was changed by the county commissioners under date of August 10, 1934, to the Edwin Shaw Sanatorium.

It was through his efforts and by the same methods that the Akron Health Department was established on a full-time functioning basis.

Mr. Shaw's singleness of purpose, integrity of character, inherent honesty, and meticulous sense of honor and justice were attributes that marked him as a leader of men.

In recognition of these services the Akron Chamber of Commerce presented him a scroll in 1940, the inscription being:

"Your contribution to the business, industrial, and social well-being of this community, over the years since 1893 when you came to Akron, has been so fundamental and so outstanding that this chamber of commerce, here assembled this ninth day of February, 1940, is honored to have this opportunity to extend to you this token of its appreciation of your distinguished accomplishments, of its gratitude for your labors, and of its assurance that the benefits from them will continue long into the future."

Mr. Shaw's will directed that the bulk of his estate be used to support charitable, health, and educational institutions in Summit County, Ohio.

In 1933 Mr. Shaw received the honorary degree of LL.D. from the

University of Akron, the fourth to receive this honor. He held the fifty-year membership badge of the A.S.M.E., having joined the Society as a junior member in 1890; he was promoted to the grade of member two years later. Many other scientific and engineering organizations, as well as civic, fraternal, and social groups, were proud to count him as a member.

Probably no man in Akron had a keener appreciation of art. He was one of the original sponsors and a faithful supporter of the Akron Art Institute and had an excellent private collection of etchings and paintings. Gardening, and particularly the cultivation of rare specimens of peonies and iris, was another of his many interests, and he was also an ardent fisherman.

Mr. Shaw is survived by his sister, Caroline Coupland Shaw, who lived with him. His wife, Jennie (Bond) Shaw, whom he married in 1898, died in 1933.

ROBERT SHIRLEY (1869–1938)

Robert Shirley was born on February 5, 1869, in Glasgow, Scotland, son of Robert and Stewart (Sterling) Shirley. He received his early education at Hutcheson's Grammar School in Glasgow and subsequently attended the technical college there and served an engineering apprenticeship with Wm. Dixon & Co. Ltd. He was employed in drafting and shop work by this company and R. Napier & Sons, also of Glasgow, for several years before coming to the United States.

In this country, his first employment was with the Rensselaer Manufacturing Company, Cohoes, N.Y., designing valves and special tools for machining them. This led to the position of mechanical engineer with the Pratt & Cady Co., Hartford, Conn., with whom he remained until 1909. During the next nine years he was works manager of the Chapman Valve Manufacturing Company, Indian Orchard, Mass., then after a brief period in consulting work in Springfield, Mass., he went to Waterford, N.Y., to become works manager of the Eddy Valve Company. Poor health forced his retirement from active work in 1922.

After a period of traveling in this country and Europe, Mr. Shirley located in East Longmeadow, Mass., later moving to Springfield, where he spent the remainder of his life. He died of a cerebral hemorrhage in the Springfield Hospital on March 4, 1938.

During the latter part of his life Mr. Shirley did some consulting work and gave a great deal of time to the fraternal organizations to which he belonged. He was a Knight Templar, 32nd degree Mason, and Shriner, and had held a number of high offices in the masonic fraternity and related orders. He also served for a number of years as president of the Springfield Automobile Club and as director of the Automobile Association of America. He had been a member of the A.S.M.E. since 1906.

Mr. Shirley was a pioneer in steel valve design for superheated steam installations and while with the Pratt & Cady Co. designed and built some nine-foot cast-iron valves for the Ontario Power Company, Niagara Falls, Canada, at that time the largest valves of that kind in the world. He invented a double-gate valve, the patent for which was assigned to the Pratt & Cady Co. He lectured in Canada and Great Britain on American valve practices, particularly in large water works and power systems.

Surviving Mr. Shirley are two sons, John G. Shirley, of North Adams, Mass., a member of the A.S.M.E., and James G. Shirley, of Springfield, as well as a number of grandchildren, a brother, and a sister. His wife, Elizabeth A. (Gilchrist) Shirley, whom he married in 1891, died in 1936.

SVERRE SKAGEN (1882–1938)

Sverre Skagen, designing engineer for the Koppers Construction Company, Pittsburgh, Pa., since 1936, died in that city on July 6 1938. His widow, Yvonne Skagen, and one child, survive him.

Mr. Skagen was born at Bergen, Norway, on December 16, 1882, son of Peter Dankertsen and Anna Sophie (Hammerstad) Skagen. He attended the Anthonisen Grammar School, Cathedral High School, and technical college in Bergen, completing the mechanical engineering course in 1903. He studied marine engineering and shipbuilding in evening school in England the following year, while working as section chief at an iron foundry in that country. Later he returned to Oslo, where he engaged in marine consulting work for a number of years, was boiler and factory inspector for the Norwegian government from 1912 to 1914, and for several years was employed as chief draftsman by a Norwegian shipbuilding company.

Since the beginning of 1924 Mr. Skagen had been employed in this country as a designer, checker, and estimator, working for various companies, including the Carnegie Steel Company, the American Sheet & Tin Plate Co., the Jones & Laughlin Steel Corp., and the Gulf Refining Company, prior to his connection with the Koppers Construction Company. He was responsible for layouts and estimates for a number of new plants for these companies, involving expenditures of many millions of dollars.

Mr. Skagen had been a member of the Norwegian Engineering Society and Engineers' Society of Western Pennsylvania, and became a member of the A.S.M.E. in 1931. He was a naturalized citizen of the United States.

WLADIMIR BORISOVICH SOUNITZA (1885–1939)

Wladimir Borisovich Sounitza, mechanical engineer for the Emsco Derrick & Equipment Co., at Los Angeles, Calif., died at the Hospital of the Good Samaritan in that city on October 10, 1939, of an embolism following an operation.

Mr. Sounitza, who became a naturalized citizen of the United States in 1930, was born at Mglin, Russia, on July 11, 1885, son of Boris Pavlovich and Marie (Mishienko) Sounitza. He was educated in Moscow, completing his high school work in 1903. He carried on studies at the Imperial High Technological Institute for the next two years and from 1909 to 1915, in which year he received a master's degree in mechanical engineering. During the years 1905–1915 he was also engaged in teaching and engineering work. For about four years he taught mathematics and physics in a private school and spent considerable time in work in his own machine shop. Then he was engineer for the Construction Department of the Chetverikoff Woolen Mill, near Moscow.

Following the completion of his engineering course, Mr. Sounitza was successively employed by the Bocharov Engineering Company, Moscow, as draftsman and designer of boiler furnaces; in the Oil Engine Department of K. Wiegand, Revel, Russia, as designing engineer; and at the Lubertzy Plant, Moscow, of the International Harvester Company as engineer in charge of the Test Department of the Oil Engine Division.

In June, 1915, Mr. Sounitza took charge of the erection and operation of the Tolvol Plant of Nobel Brothers, in Baku, Russia, and later that year was made assistant oil field superintendent by the company. In January, 1916, the company sent him to the Bibi Eibat oil fields as chief engineer, and he continued in that position until August, 1918. From then until February, 1919, he served under General Bicherahov in the war against Turkey, part of the time in charge of an automobile repair shop and part as chief engineer on a gunboat in the Caspian Sea. For his services General Bicherahov bestowed upon him the order of St. Vladimir with the Swords.

Subsequently he returned to the employ of Nobel Brothers as assistant general manager of the Bibi Eibat oil fields. The following year he became associated in the capacity of chief engineer with the Engineering Department of Azneft—the nationalized oil industry in Baku—and he continued with that organization until 1928. In 1921–1923 he was also professor at the Technological Institute in Baku. He directed the Engineering Department of Azneft from 1921 to 1923, then came to the United States to serve as consulting engineer in charge of the selection and inspection of American machinery for oil fields and machine shops in Baku. He represented the Azneft organization but not the U.S.S.R. government itself and had no connection with the financial part of the transactions.

After leaving Azneft in 1928, Mr. Sounitza spent about a year in private practice as consulting engineer on the design of oil-field equipment before entering the employ of the Emsco company as engineer designer at Los Angeles. In April, 1935, he was transferred to Houston, Texas, as chief engineer of the Machinery Division of the company there. He was recalled to Los Angeles in January, 1938.

Mr. Sounitza wrote a textbook on kinetics of mechanisms, published in Russian about 1921. He held a number of patents on oil furnaces, oil-field equipment, and electric-arc cutting apparatus. He was talented in drawing and well-informed on classical music, literature, and history.

Mr. Sounitza became an associate of the A.S.M.E. in 1924 and was given the grade of member in 1928. Surviving him are his second wife, Elisabeth Ivanovna (Postnikova) Sounitza, whom he married in 1922, and an adopted son, Vadim Wladimir Sounitza. His first wife, Nadejda (Alexandrova) Sounitza, whom he married in 1906, died in 1919.

RALPH CHARLES STIEFEL (1862–1938)

Ralph Charles Stiefel, formerly vice-president of the Aetna-Standard Engineering Company, Ellwood City, Pa., and patentee in 1895 of a disk-piercing machine for making seamless steel tubes, died at his winter home in St. Petersburg, Fla., on March 15, 1938.

Born at Oerlikon, near Zürich, Switzerland, on February 17, 1862,

Mr. Stiefel received his technical training at the Maschinenfabrik Oerlikon and Technikum Zürich, graduating from the latter in 1881. After working in Swiss silk-spinning mills for a year he was employed for several years as chief draftsman in French establishments. He returned to Zürich in 1888 and worked as draftsman for Esher Wyss & Co. until October, 1889, when he went to Great Britain to work on seamless tube projects with the British Mannesmann Tube Company, Landore, Wales.

Mr. Stiefel came to the United States in 1894 and took the position of general superintendent of the Ellwood Weldless Tube Company, Ellwood City, which was acquired by the Shelby Tube Company in 1900. He was with this organization and the National Tube Company, both of which were taken over by the U.S. Steel Corp. in 1901, until 1912.

In the fall of 1902, Mr. Stiefel helped to organize the Standard Engineering Company, Ellwood City, manufacturers of seamless steel tube mill machinery, which was merged in 1926 with the Aetna Foundry & Machine Co., of Warren, Ohio, to form the present Aetna-Standard Engineering Company, with plants in the two cities. He retired as vice-president of the company in 1932.

Mr. Stiefel became a member of the A.S.M.E. in 1897 and served for two years on the Special Research Committee on Heavy Duty Anti-Friction Bearings, being appointed when the committee was formed in March, 1929, and resigning in 1931. He was a naturalized citizen of the United States.

Surviving Mr. Stiefel are his widow, Mary (Bowen) Stiefel, whom he married in 1895, a daughter, Mrs. Howell Jenkins, of New York, N.Y., and a son, R. Charles Stiefel, Jr., of Ellwood City.

CHARLES WATERMAN STONE (1874–1938)

Charles Waterman Stone, consulting engineer for the General Electric Company and connected with that organization for nearly forty years, died at his home in Schenectady, N.Y., on February 3, 1938, of a heart ailment which had confined him to bed for nine weeks.

Mr. Stone went to work for the General Electric Company as a draftsman in August, 1899. In 1901 he was assigned to switchgear engineering work and in 1904 was transferred to the Lighting Department as assistant engineer. He was named manager of the department (now known as the Central Station Department) in 1912, and continued in that position until 1928 when, at his own request, he was relieved of managerial responsibilities and became a consulting engineer for the company.

During his early connection with the company, Mr. Stone designed all the switchgear adopted by the U.S. government for warships for some years. Later he devoted his time to the design of large vertical frequency changer sets, vertical rotary converters, and various electrical apparatus. He designed many large railway and lighting central stations throughout the country, together with much of their equipment.

Experimenting at home on new physical and mechanical problems had been one of Mr. Stone's chief hobbies since childhood, so it was natural that he took more than ordinary interest in many of the company's important developments. Perhaps his chief interest was in radio and its associated developments, particularly the photophone, a device for recording the voice or music on film, the forerunner of the talking movie. He was also active in the affairs of the Radio Corporation of America from the time of its inception, and in 1927, while still manager of the Central Station Department of the General Electric Company, was named assistant to James G. Harbord, then president of R.C.A.

Seeing the possibilities of radio and other types of vacuum tubes in additional fields of the electrical industry, he became interested in the latter years of his life in the application of thyratron tubes as a cheaper and more efficient means in the distribution and conversion of electricity from alternating to direct current and vice versa.

Mr. Stone was born in Providence, R.I., on December 24, 1874, son of Waterman and Emily Clark (Steere) Stone. He attended public school in Providence and in Kansas City, Mo., and after his graduation from high school in the latter city, spent three and one-half years at Kansas State University. From then until he became associated with the General Electric Company he worked for the Franklin Electric Company, Kansas City, Mo., and the W. S. Hill Electric Co., New Bedford, Mass., where he served an apprenticeship as machinist and toolmaker and secured drafting experience, and the Hancock Equipment Company, Boston, Mass., as foreman of its Construction Department. His work for these companies included a complete survey of the elevated railway in Kansas City, and the building of several electric roads in New England.

Mr. Stone had been a member of the A.S.M.E. since 1907. He was a fellow of the American Institute of Electrical Engineers, which he had served in committee work and as a manager and vice-president. He also belonged to The Franklin Institute, Society for the Promotion of Engineering Education, American Association for the Advancement of Science, and a number of clubs in Schenectady and New York. He was a member of Beta Theta Pi fraternity and a life member of the Navy League, and had served on the Schenectady Chamber of Commerce. He contributed numerous papers before the organizations to which he belonged and had lectured before the Engineers School, Washington, D.C., Columbia University, and other institutions. He was president of the Pioneer Thresher Co., Inc., manufacturers of agricultural implements, Shortsville, N.Y.

Surviving Mr. Stone are his widow, Harriet Anna (Westinghouse) Stone, a native of Schenectady, whom he married in 1902, and two daughters, Clara Westinghouse (Stone) Howell, and Margaret Anna (Stone) Gibson.

FRANK GIFFORD TALLMAN (1860–1938)

Frank Gifford Tallman, vice-president and director of E. I. du Pont de Nemours & Co., Wilmington, Del., at the time of his death in 1938, had been associated with that company since 1905. He served as director of purchases until March, 1916, when he was elected a director, a member of the executive committee, and vice-president in charge of purchases. In 1919 he resigned from the executive committee and was made a member of the finance committee. Also in that year he was elected president of the Du Pont Building Corporation, Hotel Du Pont Company, and Du Pont Playhouse Company. In 1925, at his own request, he was placed on the retired list, subject to call. His death occurred on April 1, 1938, at the Delaware Hospital in Wilmington, after a long illness.

Mr. Tallman was born at Dubuque, Iowa, on January 26, 1860, son of Peleg and Maria (Hudson) Tallman. His early education was secured in private and public schools in Syracuse, N.Y., and from 1873 to 1876 he attended the Syracuse Classical School. During these years he spent his leisure time helping in the shops and rolling mill of his stepfather, William Avery Sweet, brother of Professor John Edson Sweet and founder of Sweet's Manufacturing Company, Syracuse.

Upon completion of his preparatory schooling he entered Cornell University, where he studied civil and mechanical engineering for a year, being one of Professor Sweet's "Boys." During 1877–1879 he worked again in the Sweet rolling mill and spring factory and served time as an apprentice patternmaker and draftsman. He also spent some time on the road erecting Sweet's producer gas furnaces and boilers.

For a short time in 1879, Mr. Tallman was superintendent of the Farist & Windsor Co., a small steel works at Windsor Locks, Conn. Then he went to Providence, R.I., to be assistant foreman in the machine shops and also special draftsman under George H. Corliss. There he became well versed in steam engines, their theory and construction.

In the fall of 1881, at the request of his stepfather, he returned to Syracuse and during the next four years he served first as assistant superintendent and later as superintendent of Sweet's Manufacturing Company. In connection with his application for membership in the A.S.M.E. at the beginning of this period Professor Sweet wrote of him: "I know no other man of Tallman's age who has so good a combination of mechanical and executive ability and who has them under so good control."

Mr. Tallman became general superintendent of the steel mills of Carnegie-Phipps & Co. in Beaver Falls, Pa., in 1885 and continued in that position until 1890. He next spent three years as mechanical consulting engineer in Pittsburgh, Pa., designing and building wire rod mills and rolling mills. He gave this up to become Pittsburgh sales manager of the Crane and Pulley Block Department of the Yale & Towne Manufacturing Co.

For ten years, beginning in 1895, he was connected with the Brown Hoisting Machinery Company, first as sales engineer at Pittsburgh and Chicago, and subsequently as manager of the company at Cleveland. He then took up his work with E. I. du Pont de Nemours & Co.

In his early life Mr. Tallman was granted patents on glass making machinery, glass containers, and wire drawing and rolling mill machinery. An honorary degree of Master of Arts was bestowed upon him by Bowdoin College in 1935. He had excellent taste in music and played the clarinet in orchestras for many years. He collected antiques, and Lincolniana, and had some rare pieces in his extensive collection of old silver. He was an ardent golfer and a veteran traveler.

Mr. Tallman's membership in the A.S.M.E. dated from 1881 and he served as a manager of the Society from 1905 to 1908. He was a member of the Historical Society of Delaware, New England Historic Genealogical Society, Massachusetts Society of Mayflower

Descendants, and Sons of the American Revolution, as well as of many professional, sport, and social clubs. He was a member of the National and Wilmington chambers of commerce, and until recent years was chairman of the Delaware Red Cross. He was also a member of the Board of Park Commissioners, director of the Wilmington Trust Company, director of the Boys' Club of Wilmington, chairman of the advisory board of the Salvation Army, and one of the proprietors of the Wilmington and Brandywine Cemetery.

Mr. Tallman was twice married. His first wife, Annie May Dickie, whom he married in Syracuse in 1881, died in 1922. In 1929 he married Mrs. Julia Hays Ashbrook, of Wilmington, who survives him. Five children by his first wife also survive him. They are William Sweet Tallman, of Sewickley, Pa., and Frank Gifford Tallman, Jr., of Wilmington, Mrs. Irving Warner and Mrs. Thomas W. Miller, also of Wilmington, and Mrs. Louis G. Bissell, of New York, N.Y.

JOHN IBBOTTSON THOMPSON (1883–1938)

John Ibbottson Thompson, president of the Koppers Rheolaveur Company, Pittsburgh, Pa., died at his home in the Ben Avon Heights section of that city on June 25, 1938.

Mr. Thompson was born in Braddock, Pa., on December 21, 1883, son of John Thomas and Mary Jane (Ibbottson) Thompson. At an early age he moved with his parents to Youngstown, Ohio, and later to Pueblo, Colo., where his father was for many years master mason in the plant of the Colorado Fuel & Iron Co.

When fifteen years of age he left school to work as a blueprint boy in the engineering department of the Colorado Fuel & Iron Co. He soon decided that he wanted to be an engineer and, therefore, resumed and completed his high school work at night. After years of work and study he was able to enter Leland Stanford University in 1905 and was graduated as a mechanical engineer in 1909.

His first employment after graduating was with W. F. Rust in the engineering department of the Youngstown Sheet & Tube Co., in Youngstown, Ohio. A year later he was employed by the Republic Iron & Steel Co., in Youngstown, where he remained until May, 1912, and then joined the Koppers organization in Chicago.

When, in the spring of 1915, the Koppers offices were moved from Chicago, to Pittsburgh, Mr. Thompson, as chief draftsman, with W. F. Rust as chief engineer, was faced with the task of building up the small nucleus of some fifteen engineers and draftsmen brought from Chicago, to one of the largest engineering organizations in the country. After two years the department had grown to over 300 employees and in August, 1927, it reached a peak of 730. Great administrative and engineering problems had to be met and successfully solved in organizing such a steadily growing force into a smoothly working assembly of well co-ordinated units. At the same time he had to establish the engineering principles governing the design of Koppers coke and gas plants to meet the standards already adopted for steel mill and power plant design.

Due to his recognized ability, Mr. Thompson was soon entrusted with greater responsibility. He served successively as assistant chief engineer, chief engineer, and vice-president in charge of engineering, construction, and purchasing, during one of the most active periods in the company's history.

At the time the Koppers Building was being planned, he, in addition to his other duties, served as chairman of the building committee and in this capacity was largely responsible for the successful completion of the entire building program.

When it was found desirable for Koppers to extend its activities to include coal washing plants, he was a member of the committee to investigate available processes. Largely due to his recommendations, the Rheolaveur Company was acquired and Mr. Thompson served, first, as vice-president and, since 1932, as president of the reorganized company, known as the Koppers Rheolaveur Company. As president, he devoted his entire time and effort to the management of the company and the establishment of its policies. During this period, through development work conducted under his direction, improvement in coal washing was accomplished and large coal preparation plants were constructed in the principal coal mining areas of the country.

Mr. Thompson took an active part in the community affairs in Ben Avon. He was responsible for much of the development work in connection with Ben Avon Heights and as first president of the Shannopin Golf Club, was an able leader in the organization of the club and the building of the club house and golf course. He was an active member of the Ben Avon Methodist Episcopal Church, which, at the time of his death, he was serving as president of its Board of Trustees.

Shortly after his graduation from Leland Stanford University, he married Adelaide Tillson, who survives him, with their two daughters, Mrs. Ruth Findlay and Jane Clare Thompson. He is also survived by three brothers, Frank, Peter B., and Carl Thompson.

Mr. Thompson had been a member of both the A.S.M.E. and the American Institute of Mining and Metallurgical Engineers since 1918. He also belonged to the Engineers' Society of Western Pennsylvania, Eastern States Blast Furnace and Coke Oven Association, and American Iron and Steel Institute, as well as to the Sigma Xi fraternity and the Duquesne Club of Pittsburgh and Medinah Country Club of Chicago.—[Adapted from a tribute in the *Koppers News*, August, 1938.]

ELIHU THOMSON (1853–1937)

In Swampscott, Mass., on March 13, 1937, death came to Professor Elihu Thomson, a few days before his 84th birthday. In his death there passes away the last member of that brilliant group of scientists and inventors who, in such amazingly rapid succession, discovered new fundamental scientific truths, contrived new theories and working hypotheses, and applied them to such a myriad of practical uses that they veritably started a new era. The names of Edison, Thomson, Steinmetz, and Westinghouse will ever be associated with the beginning and the early rapid growth of the adaptation of electricity to the industry, homes, and farms of America.

But Thomson, like the other three, by no means confined his genius to the electrical field. The fields of mechanical engineering, chemistry, and even astronomy were enriched by discoveries, applications, and improvements which constantly flowed from his laboratory as the result of his inspired thinking and brilliant experimentation. His early interests included the uniflow steam engine, the cream separator, and the automobile muffler. He made important contributions to the art of the heat treatment of steel, and was the first to propose the use of a mixture of helium and oxygen for workers in caissons and tunnel borings. For the field of astronomy he developed fused quartz for use in lenses and mirrors.

It is, however, for his achievements in the electrical field that he is best known. The three-coil dynamo, the Thomson electric meter, the resistance welder, and the alternating-current repulsion motor, are probably the best known of his inventions, but he was so prolific in this field that at his death he held the third largest number of patents ever issued to one inventor.

Professor Thomson was born in Manchester, England, on March 29, 1853, coming to the United States when he was 5 years old. Graduating from the Boys' Central High School, Philadelphia, at the age of 18, he became an instructor there, and so outstanding was his work that at the age of 23 he was made professor. Throughout these early years he was constantly conducting original experiments, mainly in electricity, making one invention after another, and delighting audiences by his astonishing demonstration lectures. It was during these early days that he antedated Hertz by over ten years and foreshadowed radio communication by sending wireless waves from one room to another through intervening walls and partitions.

In 1880, together with Professor Edwin J. Houston, also of the Philadelphia Central High School, and Edwin Wilbur Rice, Jr., one of their former pupils, he joined the newly formed American Electric Company in New Britain, Conn., forerunner of the Thomson-Houston Electric Company, which was established in Lynn, Mass., three years later. In 1892 this business was combined with the Edison General Electric Company to form the General Electric Company, Professor Thomson becoming the head of the now world-famous Thomson Research Laboratory. Here he continued his scientific investigations and development work up to about a year before his death, when his health began to fail. Throughout this long period, scientific discoveries and practical inventions continued to flow in an amazing stream from his active fertile brain. But he shunned publicity and his name rarely appeared in newspaper headlines, so the general public knew little of him. That the scientific and engineering world appreciated his greatness is attested by the numerous honorary degrees and medals conferred upon him by the outstanding scientific bodies of both Europe and America. From Great Britain he received the three most coveted scientific awards, the Hughes Medal of the Royal Society, the Lord Kelvin Medal, and the Faraday Medal. He was made chevalier and officer of the Legion of Honor of France, and was the second American to receive the Medal of Honor of the Verein Deutscher Ingenieure. In America, The Franklin Institute twice awarded him the John Scott Medal, and presented him with the Elliot Cresson Gold Medal and the Franklin Medal. He lectured before the Institute and the Thomson exhibit in its museum contains apparatus from the famous laboratory where he spent so much of his life. He also received the Rumford Medal of the American Academy of Arts and Sciences, and the John Fritz Medal of the four founder engineering societies.

As further evidence of appreciation, he was elected honorary mem-

ber of The A.S.M.E. in 1930, and had held the office of president of the American Institute of Electrical Engineers, the International Electrical Congress, and the International Electrotechnical Commission.

Professor Thomson was deeply interested in the Massachusetts Institute of Technology, serving as non-resident professor of electrical engineering, life member of the Corporation, and for over two years its acting president.

Honored by several great universities with the degree of Doctor, he preferred the simple title of Professor. "It is more friendly," he said. This is indicative of the man. His life was simple, his attitude friendly and unselfish, exemplifying the very spirit of co-operation and helpfulness. With a true scientist's and engineer's unselfish devotion to the common good, he took such an active part in civic and community affairs, that it won for him the confidence and enduring love of his fellow townsmen.—[Memorial prepared by Professor WILLIAM H. TIMBIE, Department of Electrical Engineering, Massachusetts Institute of Technology, Cambridge, Mass.]

EDWARD F. VOLKMER (1867–1934)

Edward F. Volkmer, who became a member of the A.S.M.E. in 1930, and whose death occurred on October 3, 1934, was a native of Germany. He was born at Seelow on November 27, 1867, and was educated in Germany, attending a technical high school in Berlin for a year and a half. For some fifteen years he was employed in that city, working for various firms, including Siemens & Halske and the C. P. Goerz Optical Co. Then he was at the Maxim gun works, Erith, Kent, England, for two and a half years.

The year in which Mr. Volkmer came to the United States is not known, but in 1906 he started a business here, it is thought in Newark, N.J., for the design and manufacture of automatic machinery and scientific instruments in the mechanical and electrical fields. This was later incorporated as the Volkmer Electrical Company, but reverses forced the company out of business. Between 1910 and 1918, when he reestablished himself in Newark as an independent designer and builder of automatic labor saving machinery, Mr. Volkmer served successively as superintendent of the Herschede Hall Clock Company, Cincinnati, Ohio, designing engineer for the Singer Sewing Machine Company, Elizabethport, N.J., and American Machine & Foundry Co., Brooklyn, N.Y., and superintendent of J. Mills Co., Brooklyn.

Mr. Volkmer's organization was known as E. F. Volkmer & Sons, Inc., until about 1930, when it became the Volkmer Radio Products Corporation, of which he was president and general manager. At that time he reported that a branch was being opened in Chicago, Ill. Whether this plan was carried out is not known, but in 1931 or 1932 the Volkmer Manufacturing Company, for the manufacture of special radio wire, was established in Long Island City, N.Y. After his death, this business was continued for a time by his son, Paul R. Volkmer.—[Biography compiled from best obtainable information, not all of which could be verified.]

EDGAR WHITE WAGENSEIL (1884–1938)

Edgar White Wagenseil, sales manager of the Hagan Corporation, Pittsburgh, Pa., and a resident of the Oakmont Section of that city, died suddenly on May 10, 1938, while engaged in his official duties.

Mr. Wagenseil was born at Port Huron, Mich., on November 16, 1884, son of George O. and Mary Adelia (White) Wagenseil. He attended the Port Huron schools and was graduated from the University of Illinois in 1905, with a B.S. degree in mechanical engineering. During the following summer he was employed by the B. F. Sturtevant Co., Chicago, as draftsman on indirect heating systems, then he became assistant to the master mechanic of the Illinois Steel Company at their South Works, Chicago, where he remained until June, 1907. The next six months were spent with the Warren Webster Company, Chicago, as salesman and draftsman on heating and ventilating installations.

In November, 1907, Mr. Wagenseil was made a deputy smoke inspector for the City of Chicago, and for two years he was engaged in various combustion engineering problems connected with that position. He then became sales manager and combustion engineer for the Burke Furnace Company, Chicago, in direct charge of furnace and stoker installations and boiler tests, and continued with that company until the United States entered World War I. As a lieutenant (junior grade) in the Naval Reserve Force, he served from July, 1918, to February, 1919, in the Naval Air Force in connection with the assembly and repair of Liberty motors, being stationed at a Reserve Flying Corps Repair Base in France part of the time.

After the war Mr. Wagenseil was employed for about two years by the Westinghouse Electric & Manufacturing Co. as district stoker engineer at Chicago. Subsequently he spent several years on sales of the Harrington stoker, first as sales manager for the Brady Foundry Company, later as district manager for the United Machine & Manufacturing Co., both in Chicago. When the latter was acquired by the Riley Stoker Corporation in 1924, he became secretary and treasurer of the Buckeye Dryer Company, Chicago. From 1927 to 1932 he was sales engineer for the Blaw-Knox Company, of Pittsburgh, Pa., handling air preheaters for the steel industry.

Mr. Wagenseil had been connected with the Hagan Corporation, combustion and chemical engineers, since 1932, serving first as sales engineer and later as general sales manager for the company and its subsidiaries, the Buromin Company and Hall Laboratories, Inc.

Mr. Wagenseil had been a member of the A.S.M.E. since 1916 and also belonged to the Engineers' Society of Western Pennsylvania, and to the Iron and Steel Electrical Engineers, and the Pittsburgh Field Club. He is survived by his widow, Ruth B. (Taylor) Wagenseil, whom he married in 1907, a son, John White Wagenseil, and a daughter, Martha.

LEE EARL WALKER (1881–1937)

Lee Earl Walker, district manager in charge of sales for the Good Roads Machinery Corporation's branch office at Philadelphia, Pa., died on December 18, 1937. The son of Curtis M. and Nancy Jane (Burleigh) Walker, he was born on August 10, 1881, in Johnstown, Pa., and attended public schools there and in Altoona, Pa. He served an apprenticeship as a machinist with the Pennsylvania Railroad, at Altoona, from 1899 to 1902, and then worked for nearly a year for the Westinghouse Machine Company, Pittsburgh, Pa., building gas and steam engines. From July, 1903, to January, 1905, he was employed by the Baldwin Locomotive Works, Philadelphia, Pa., as foreman of locomotive construction. During the next two years he was foreman of general locomotive repairs for the Atchison, Topeka & Santa Fe R.R. at Needles and San Bernardino, Calif. A survivor of the Johnstown flood as a boy, he also experienced the San Francisco earthquake during this period of employment in California.

In January, 1909, Mr. Walker returned to the Baldwin Locomotive Works, where he remained for about three years. At first he was night foreman of the erecting shop, then final engine inspector at the 26th Street shop. Later he went to the new Eddystone shops as assistant to the general foreman of the erecting department, and finally he was appointed traveling engineer, to set up locomotives and try them out on grade and tonnage tests on various railroads.

From early in 1912 until the latter part of 1914, Mr. Walker was connected with the American Road Machinery Company, Groton, N.Y., as assistant to the vice-president and general manager of the company, in direct charge of the entire plant. His duties included the design of jigs and fixtures, testing of machinery, and supervision of the drafting department, in addition to manufacturing. Early in 1915 Mr. Walker was transferred to the office of the Good Roads Machinery Company, in Philadelphia, the selling organization, as salesman and sales engineer. The following year he was made district salesman for this company, with headquarters in Washington, D.C.

During the World War period, 1917–1919, Mr. Walker served in the Ordnance Reserve Corps, advancing from the rank of first lieutenant to that of major. He was ordered to active duty in the Production Division of the Ordnance Department at Washington in October, 1917, and was officer in charge of the production of ordnance matériel at various plants during the following year. He was stationed at Amatol, N.J., in connection with the construction and operation of a shell-loading plant for several months following the Armistice, and from then until August, 1919, was on the staff of the commanding officer at the Amatol Arsenal, in charge of the Storage, Traffic, and Construction Department.

Mr. Walker returned to civilian life as district sales engineer and assistant manager of the Good Roads Machinery Company's branch office at Philadelphia. The Good Roads Machinery Corporation was incorporated in 1932, acquiring the Good Roads Machinery Company and also the American Road Machinery Company, and Mr. Walker continued with the organization as distributor until his death.

Mr. Walker became an associate of the A.S.M.E. in 1916; and associate-member in 1921; and was automatically promoted to the member grade in 1935. He was a member of the Engineers Club of Philadelphia, Philadelphia Art Club, and the Montgomery Lodge, in Philadelphia, of the masonic fraternity, in which order he held the 32nd degree. His main interest outside his work was his summer home, a farm in the Pocono Mountains.

Mr. Walker was twice married. He is survived by his second wife, Gertrude O. (Ferguson) Walker, and by two children, Sydney Lee Walker and Mrs. Juanita (Walker) Pelka.

Indexes to A.S.M.E. Papers and Publications

THIS and the following pages will serve as a guide to the current publications of the A.S.M.E. during the calendar year 1942 and also to publications developed by technical committees.

Regular Society Publications, 1942

Mechanical Engineering, monthly (see index on page RI-85)
A.S.M.E. Transactions, monthly (see index on page RI-95)
Mechanical Catalog and Directory, 1943 edition

Special Publications Issued in 1942

I.S.A. Tolerance System
1941 Oil Engine Power Cost Report
1942 Proceedings of the Oil and Gas Power Division
Surface Finish

American Standards

1942 Supplement to 1937 Safety Code for Elevators
C. I. Screwed Drainage Fittings
Pipe Threads
Code for Pressure Piping
Letter Symbols for Hydraulics
Letter Symbols for Mechanics of Solid Bodies

A.P.I.-A.S.M.E. Code for Unfired Pressure Vessels

1942 Addenda

Boiler Construction Code

1942 Addenda to:
- Locomotive Boiler Code
- Low Pressure Heating Boilers
- Miniature Boiler Code
- Power Boiler Code
- Unfired Pressure Vessel Code
- Specifications for Materials

Power Test Codes

Supplement to Hydraulic Prime Movers

Auxiliary Sections

Part 2, Pressure Measurement, Chapter 5, Liquid Column Gages
Part 12, Measurement of Time
Part 21, Leakage Measurements

How to Find Papers Presented at 1942 A.S.M.E. Meetings

THE technical programs of the meetings of the Society and of its Professional Divisions have been published in *Mechanical Engineering* and may be located by consulting the index on pages RI-85–94. A majority of these papers were published, or will be published, in *Mechanical Engineering* or the Transactions (including the *Journal of Applied Mechanics*) and may be located by reference to the indexes of these publications. Several additional papers and reports included in these 1942 programs were not published during the year in Transactions or *Mechanical Engineering* but were issued in mimeographed or photo-offset form.

Complete sets of these are on file for reference purposes at the office of the Society and the Engineering Societies Library, under the title of "Miscellaneous Papers Presented at A.S.M.E. Meetings, 1942." Photostat copies of any of the papers may be secured from the Library at twenty-five cents a page to members, or thirty cents a page to nonmembers.

Publications Developed by the Technical Committees

THE Society's technical committees, the first of which was organized many years ago and all of which have been continuously at work on codes, standards, research, and other special reports, have developed a series of publications of permanent value to the membership. The following list is presented here for record and for ready reference. This list covers the entire group of publications of these committees completed to date which are now available.

To assist the members in securing copies of these publications the sale price is also given. A discount of 10 per cent is allowed to A.S.M.E. members on standards and a 20 per cent discount on all other publications except where otherwise noted.

A.S.M.E. AMERICAN STANDARDS

Bolt, Nut, and Rivet Proportions

Large Rivets (B18.4—1937), $0.65
Plow Bolts (B18f—1928), $0.35
Round Unslotted-Head Bolts (B18.5—1939), $0.50
Slotted-Head Proportions: Machine Screws, Cap Screws, and Wood Screws (B18c—1930), $0.45
Small Rivets (B18a—1927), $0.30
Socket Set Screws and Socket-Head Cap Screws (B18.3—1936), $0.40
Tinners', Coopers', and Belt Rivets (B18g—1929), $0.35
Track Bolts and Nuts (B18d—1930), $0.40
Wrench-Head Bolts and Nuts and Wrench Openings (B18.2—1941), $0.65

Piping and Pipe Fittings

Brass Fittings for Flared Copper Tubes (A40.2—1936), $0.35
Cast-Iron Pipe Flanges and Flanged Fittings for 25 Lb Maximum Saturated Steam Pressure (B16b2—1931), $0.40
Cast-Iron Pipe Flanges and Flanged Fittings for 125 Lb Maximum Saturated Steam Pressure (B16a—1939), $0.60
Cast-Iron Pipe Flanges and Flanged Fittings for 250 Lb Maximum Saturated Steam Pressure (B16b—1928), $0.50
Cast-Iron Pipe Flanges and Flanged Fittings for 800 Lb Maximum Hydraulic Pressure (B16b1—1931), $0.35
Cast-Iron Soil Pipe and Fittings (A40.1—1935), $0.65
Cast-Iron Long Turn Sprinkler Fittings for 150 and 250 Lb Maximum Saturated Steam Pressure (B16g—1929) and Addendum (B16g1—1937), $0.50
Cast-Iron Screwed Fittings for 125 and 250 Lb Maximum Saturated Steam Pressure (B16d—1941), $0.40
Cast-Iron Screwed Drainage Fittings (B16.12—1942), $0.45
Code for Pressure Piping (B31.1—1942), $2.00
Face-to-Face Dimensions of Ferrous Flanged and Welding End Valves (B16.10—1939), $0.55
Malleable-Iron Screwed Fittings for 150 Lb Maximum Saturated Steam Pressure (B16c—1939), $0.50
Pipe Plugs (B16e2—1936), $0.35
Pipe Threads (B2.1—1942), $0.75
Scheme for the Identification of Piping Systems (A13—1928), $0.50
Steel Pipe Flanges and Flanged Fittings for 150 to 2500 Lb Maximum Steam Service Pressure (B16e—1939), $1.25

Soldered-Joint Fittings (A40.3—1941), $0.45
Steel Butt-Welding Fittings (B16.9—1940), $0.40
Wrought-Iron and Wrought-Steel Pipe (B36.10—1939), $0.50

Letter and Graphical Symbols and Charts

Abbreviations for Scientific and Engineering Terms (Z10.1—1941), $0.35
Drawings and Drafting-Room Practice (Z14.1—1935), $0.50
Engineering and Scientific Charts for Lantern Slides (Z15.1—1932), $0.50
Graphical Symbols for use on Drawings in Mechanical Engineering (Z32.2—1941), $0.50
Letter Symbols for Hydraulics (Z10.2—1942), $0.35
Letter Symbols for Mechanics of Solid Bodies (Z10.3—1942), $0.25
Letter Symbols for Heat and Thermodynamics (Z10c—1931), $0.30
Letter Symbols for Photometry and Illumination (Z10d—1930), $0.20
Time Series Charts (Z15.2—1938), $1.25

MISCELLANY

Fire-Hose Coupling Screw Thread (B26—1925), $0.25
Gear Materials and Blanks (B6.2—1933), $0.50
Hose Coupling Screw Threads (B33.1—1935), $0.25
Indicating Pressure and Vacuum Gages (B40—1939), $0.40
Preferred Thickness for Uncoated Thin Flat Metals (B32.1—1941), $0.25
Rolled Threads for Screw Shells of Electric Sockets and Lamp Bases (C44—1931), $0.35
Shaft Couplings (B49—1932), $0.35
Spur Gear Tooth Form (B6.1—1932), $0.45

Small Tools and Machine Tool Elements

Machine Tapers (B5.10—1937), $0.50
Milling Cutters (B5c—1930), $0.75
Taps—Cut and Ground Threads (B5.4—1939), $1.25
Terminology and Definitions for Single-Point Cutting Tools (B5.13—1939), $0.40
Adjustable Adapters (B5.11—1937), $0.50
Chucks and Chuck Jaws (B5.8—1936), $0.45
Circular and Dovetail Forming Tool Blanks (B5.7—1936), $0.40
Involute Splines, Side Bearings (B5.15—1939), $0.65
Jig Bushings (B5.6—1941), $0.35
Lathe Spindle Noses (B5.9—1936), $0.50
Reamers (B5.14—1941), $0.75
Rotating Air Cylinders and Adapters (B5.5—1932), $0.35
Tool Holder Shanks—Tool Post Openings (B5b—1929), $0.25
T-Slots, Their Bolts, Nuts, Tongues, and Cutters (B5a—1941), $0.35
Twist Drills (B5.12—1940), $0.55
Code for Design of Transmission Shafting (B17c—1927), $0.75
Shafting and Stock Keys (B17.1—1934), $0.45
Screw Threads for Bolts, Nuts, Machine Screws, and Threaded Parts (B1.1—1935), $0.60
Screw Thread Gages and Gaging (B1.2—1941), $0.60
Acme and Other Translating Threads (B1.3—1941), $0.45
Tolerances, Allowances, and Gages for Metal Fits (B4a—1925), $0.50
Woodruff Keys, Keyslots, and Cutters (B17f—1930), $0.35

BOILER CONSTRUCTION CODE

1942 Addenda to:
- Locomotive Boiler Code, $0.50
- Low-Pressure Heating Boilers, $0.50
- Miniature Boiler Code, $0.15
- Power Boiler Code, $0.45
- Unfired Pressure Vessel Code, $0.50
- Specifications for Materials, $0.85

Boiler Code Interpretation Service, $5.00 annually
API-ASME Code for Unfired Pressure Vessels
1942 Addenda, $0.40

POWER TEST CODES AND AUXILIARY SECTIONS

Test Codes for

Atmospheric Water-Cooling Equipment (1930), $0.45
Compressors and Exhausters (1935), $0.95
Displacement Compressors, Vacuum Pumps, and Blowers (1939), $0.75
Dust Separating Apparatus (1941), $0.90
Evaporating Apparatus (1941), $0.50
Feedwater Heaters (1927), $0.35
Gas Producers (1928), $0.55
Hydraulic Prime Movers (1938 with 1942 Addenda), $0.60
Internal-Combustion Engines (1930), $0.55
Liquid Fuels (1930), $0.35
Reciprocating Steam Engines (1935), $0.65
Reciprocating Steam-Driven Displacement Pumps (1927), $0.65
Refrigerating Systems (1927), $0.55
Solid Fuels (1931), $0.55
Speed-Responsive Governors (1927), $0.45
Stationary Steam-Generating Units (1936), $0.60
Steam Condensing Apparatus (1938), $0.65
Steam Locomotives (1941), $0.55
Steam Turbines (1941), $2.50

Auxiliary Sections

General Instructions (1929), $0.35
Definitions and Values (1931), $0.40
Part 1—General Considerations (1935), $0.35.
Part 2—Pressure Measurement
- Chapter 1, Barometers; Chapter 6, Tables, Multipliers, and Standards (1941), $0.60
- Chapter 2, Static and Total Pressure, Static Holes and Tubes, and Chapter 3, Pipes for Pressure Measurement (1936), $0.65
- Chapter 4, Bourdon, Bellows, Diaphragm, and Deadweight Gages (1938), $0.65
- Chapter 5, Liquid Column Gages (1942), $0.75

Part 3—Temperature Measurement
- Chapter 1, General; Chapter 5, Pyrometric Cones; Chapter 6, Liquid-in-Glass Thermometers; and Chapter 7, Bourdon Tube Thermometers (1931), $0.75
- Chapter 2, Radiation Pyrometers (1936), $0.55
- Chapter 3, Thermocouple Thermometers or Pyrometers (1940), $0.65
- Chapter 8, Optical Pyrometers (1940), $0.35

Part 4—Head Measuring Apparatus (1933), $0.35
Part 5, Chapter 4—Flow Measurement by Means of Standardized Nozzles and Orifice Plates (1940), $2.75
Part 6—Electrical Measurements (1934), $1.25
Part 8—Measurement of Indicated Horsepower (1941), $0.75
Part 9—Heat of Combustion (1932), $0.40
Part 10—Flue and Exhaust Gas Analyses (1936), $1.35
Part 11—Determination of Quality of Steam (1931), $0.45
Part 12—Measurement of Time (1942), $0.40
Part 13—Speed Measurements (1939), $0.45
Part 14—Linear Measurements (1936), $0.55
Part 15—Measurement of Surface Areas (1937), $0.75
Part 16—Density Determinations (1931), $0.30
Part 17—Determination of the Viscosity of Liquids (1931), $0.45
Part 18—Humidity Determinations (1932), $0.50
Part 20—Smoke-Density Determinations (1936), $0.65
Part 21—Leakage Measurements (1942), $0.60

RESEARCH

Fluid Meters:
- Part 1—Theory and Application (1937), $3.00
- Part 2—Description of Meters (1931), $1.75
- Part 3—Selection and Installation (1933), $1.50

Report of the A.G.A.-A.S.M.E. Committee on Orifice Coefficients (1935), $2.75
Tests on Electrical Equipment for Drilling Rotary Drilled Oil Wells (1933), $0.85
Tests on Steam Equipment for Drilling Rotary Drilled Oil Wells (1932), $0.85
Bibliography on Cutting of Metals (1866–1930), $1.25
Bibliography on Deterioration of Condensing Equipment (1845–1930), $1.25
Bibliography on Effect of Temperature Upon Properties of Metals (1928–1931), $1.25
Bibliography on Management Literature and Supplement (1903–1935), $2.75
Bibliography on Mechanical Springs (1678–1927), $1.25
Bibliography on Woods of the World (1928), $1.25
Bibliography on Marketing Research (1935), $1.00
Bibliography on Machining of Wood (1939), $1.25

SAFETY CODES

Safety Code for Elevators (A17.1—1937 with 1942 Supplement) (10 per cent discount), $1.00
Elevator Inspectors' Manual (A17.2—1937) (10 per cent discount), $0.75

Safety Code for Mechanical Power-Transmission Apparatus (10 per cent discount) (B15—1927), $0.35
Compressed-Air Machinery and Equipment (B19—1938), $0.30

BIOGRAPHIES

BIOGRAPHIES issued under the sponsorship of the A.S.M.E. Biography Committee are as follows:

Autobiography of John A. Brashear (1924), $5.00
Autobiography of an Engineer, by W. LeR. Emmet (1940), $3.50
Autobiography of John Fritz (1940), $3.25
Biography of James Hartness, by Joseph W. Roe (1937), $4.00
Biography of Fred J. Miller (1941), $1.00
Biography of John Stevens, by Archibald Douglas Turnbull (1928), $5.00
Biography of John Edson Sweet, by A. W. Smith (1925), $4.50
Biography of Robert Henry Thurston, by William F. Durand (1929), $5.00
Life of Henry Laurence Gantt, by L. P. Alford (1934), $5.00

BOOKS ON SPECIAL SUBJECTS

Aeronautical Dictionary (1929), $1.65
Corrosion-Resistant Metals (1936), $1.25
Engineering's Part in the Development of Civilization (1939), $1.50
Flow of Water in Pipes and Pipe Fittings (1941), $8.00
General Discussion on Lubrication (1938) (no discount), $6.50
Hydraulic Laboratory Practice (1929), $10.00
Hydraulic Structures (1937), $18.00
I.S.A. Tolerance System (1942), $2.50
Manual on Cutting of Metals (1939), $5.00
1943 A.S.M.E. Mechanical Catalog and Directory, $3.00 (set gratis to members upon request)
1941 Oil Engine Power Cost Report (1942), $1.25
Sixty Year Index to A.S.M.E. Technical Papers (1941), $3.75
Surface Finish (1942) (no discount), $3.25
Theoretical Steam Rate Tables (1937), $1.25

PERIODICALS

*Mechanical Engineering**—Annual Subscription rate in United States $6; to Canada $6.75; elsewhere, $7.50
A.S.M.E. Transactions,* including *Journal of Applied Mechanics*, Annual subscription rate in United States, $12, elsewhere, $12.75

* Subscription price included in A.S.M.E. membership dues.
